"*The American Medical Association, though formally accepting and publishing the reports of the various Standing Committees (and Sections), holds itself wholly irresponsible for the opinions, theories or criticisms therein contained, except otherwise decided by special resolution.*"—TRANSACTIONS, 1851.

GIFT OF
JOSEPH HENRY HEWITT.

OFFICERS OF THE AMERICAN MEDICAL ASSOCIATION

1901-1902

GENERAL OFFICERS

President—John A. Wyeth	New York
First Vice-President—Alonzo Garcelon	Maine
Second Vice-President—A. J. Stone	Minnesota
Third Vice-President—A. F. Jonas	Nebraska
Fourth Vice-President—John A. Dibrell	Arkansas
Secretary—George H. Simmons	61 Market St., Chicago, Illinois
Treasurer—Henry P. Newman	100 Washington St., Chicago, Illinois
Librarian—George W. Webster	Illinois
Chairman Com. of Arrangements—G. F. Comstock	Saratoga Springs, N. Y.

BOARD OF TRUSTEES.

E. E. Montgomery, 1703 Walnut St., Philadelphia, 1902.
H. L. E. Johnson, 1821 Jefferson Place, Washington, D. C., 1902.
Joseph M. Mathews, Louisville, Ky., 1902.
Miles F. Porter, Ft. Wayne, Ind., 1903.
E. Fletcher Ingals, 36 Washington St., Chicago, 1903.
W. L. Rodman, 1626 Spruce St., Philadelphia, 1903.
John F. Fulton, St. Paul, Minn., 1904.
T. J. Happel, Trenton, Tenn., 1904.
W. W. Grant, Denver, Colo, 1904.

JUDICIAL COUNCIL.

Term expires 1902: J. D. Griffith, Missouri; P. H. Bailhache, Marine-Hospital Service; J. E. Cook, Ohio; J. P. Lewis, Kansas; F. H. Wiggin (Secretary), New York; J. W. Irwin, Kentucky; Walter Wyman, District of Columbia. Term expires 1903: James R. Guthrie, Iowa; G. P. Gillespie, Tennessee; R. C. Moore, Nebraska; Ida J. Heiberger, District of Columbia; John B. Roberts, Pennsylvania; Charles S. Rodman (Chairman), Connecticut; S. L. Jepson, West Virginia. Term expires 1904: Geo. Cook, New Hampshire; H. H. Grant, Kentucky; John B. Murphy, Illinois; Philip Marvel, New Jersey; Louis H. Taylor, Pennsylvania; John L. Dawson, South Carolina; N. Fred Essig, Washington.

SECTION OFFICERS

PRACTICE OF MEDICINE—Chairman, Frank A. Jones, Memphis, Tenn.; Secretary, Robert B. Preble, Chicago. Executive Committee—Frank Billings, Chicago; George Dock, Ann Arbor, Mich.; J. M. Anders, Philadelphia.

OBSTETRICS AND DISEASES OF WOMEN—Chairman, J. H. Carstens, Detroit; Secretary, C. L. Bonifield, Cincinnati. Executive Committee—A. H. Cordier, Kansas City; W. E. B. Davis, Birmingham, Ala.; Henry P. Newman, Chicago.

SURGERY AND ANATOMY—Chairman, DeForest Willard, Philadelphia; Secretary, James B. Bullitt, Louisville. Executive Committee—W. J. Mayo, Rochester, Minn.; H. O. Walker, Detroit; J. J. Ochsner, Chicago.

HYGIENE AND SANITARY SCIENCE — Chairman, Arthur R. Reynolds, Chicago; Secretary, H. M. Bracken, Minneapolis, Minn. Executive Committee—W. C. Woodward, Washington, D. C.; Ernest Wende, Buffalo, N. Y.

OPHTHALMOLOGY—Chairman, Frank Allport, Chicago; Secretary, C. A. Veasey, Philadelphia. Executive Committee—Casey A. Wood, Chicago; H. V. Würdeman, Milwaukee; J. A. Lippincott, Pittsburg, Pa.

DISEASES OF CHILDREN—Chairman, H. M. McClanahan, Omaha, Neb.; Secretary, Frank X. Walls, Chicago. Executive Committee—H. E. Tuley, Louisville; Edwin Rosenthal, Philadelphia; Samuel W. Kelley, Cleveland, Ohio.

STOMATOLOGY—Chairman, A. H. Peck, Chicago; Secretary, Eugene S. Talbot, Chicago. Executive Committee—G. V. I. Brown, Milwaukee; M. H. Fletcher, Cincinnati; R. R. Andrews, Cambridge, Mass.

NERVOUS AND MENTAL DISEASES—Chairman, J. T. Eskridge, Denver; Secretary, F. Savary Pearce, Philadelphia. Executive Committee—Frederick Peterson, New York City; Hugh T. Patrick, Chicago; H. A. Tomlinson, St. Peter, Minn.

CUTANEOUS MEDICINE AND SURGERY—Chairman, Henry W. Stelwagon, Philadelphia; Secretary, R. R. Campbell, Chicago. Executive Committee—W. T. Corlett, Cleveland; L. Duncan Bulkley, New York City; W. L. Baum, Chicago.

LARYNGOLOGY AND OTOLOGY—Chairman, G. Hudson Makuen, Philadelphia; Secretary, J. F. Barnhill, Indianapolis. Executive Committee—Emil Mayer, New York City; C. R. Holmes, Cincinnati; J. N. Mackenzie, Baltimore.

MATERIA MEDICA, PHARMACY AND THERAPEUTICS—Chairman, George F. Butler, Alma, Mich.; Secretary, C. S. N. Hallberg, Chicago. Executive Committee—Thos. Hunt Stucky, Louisville; Leon L. Solomon, Louisville; N. S. Davis, Jr., Chicago.

PHYSIOLOGY AND PATHOLOGY—Chairman, Frank B. Wynn, Indianapolis; Secretary, W. T. Howard, Cleveland. Executive Committee—A. Stengel, Philadelphia; W. S. Hall, Chicago; L. Hektoen, Chicago.

GENERAL INDEX.

Use of the index will be facilitated by bearing in mind that subjects are frequently given under two or more headings, e. g., brain, cerebral, tumors, etc.; heart and cardiac; cirrhosis, liver and hepatic; child, children and infant; gland, thyroid, etc. Often, too, writers treat of the eye, ear, nose and throat under one head, etc., and the titles do not always permit of indexing under the several headings. The "General Index" contains only titles of articles, editorials, society reports, abstracts, and miscellaneous matter appearing in The Journal; the book notices, deaths, societies, marriages, authors, and titles of articles mentioned in the "Current Medical Literature" department are indexed and arranged under their separate headings instead of in the body of the "General Index."

- bbott, A. C., bacteria of diphtheria, 1495
- Abdomen, contusions of, 1427
  - need of more thorough physical examination of, 909
- Abdominal operations, pus in, 1651
  - obstruction, auto-reduction of hernia as cause of, 1076
  - section, closure of incision in, 1147
  - wall, resection of pendulous, 921
- Abortifacient drug, nature of, immaterial, 1658
- Abortion cases, indictment and declarations in, 209
  - criminal, and dying declarations, 918
- Abrams, R., exophthalmic goiter of syphilitic origin, 466
- Abscess, appendicular, 128
  - cerebral, 1075, 1123
  - kidney, 1811
  - of liver, 1319
  - of lung, 590
  - orbital, 51
  - otitis extradural, 1430
  - peritonsillar, 1739
  - periurethral, 1281
  - retroperitoneal of appendicular origin, 128
  - retropharyngeal, 408
  - subphrenic, 1416
- Abscesses, artificial, 994
  - brain, multiple, 767
  - evacuation of, in retro-vesical pouch, 477
  - spinal, 141
  - walled off, 27
- Absorbent, unbroken skin as, 250
- Abt, I. A., floating kidneys in *children*, *1166*
- Academie de medicine, prizes offered by, 199
- Accouchement forcé in placenta previa, 1653
- Account, proof of, 839
- Acetone, auto-observation of, 1286
- Achillotomy, plastic, 353
- Acid, carbolic, 1661
  - intoxication and diabetic coma, 1414
  - trichloracetic, 290
- Acne *rosacea, treatment of*, with adrenal extract, 1658
  - of face, prescription for treatment of, 763
  - rosacea, prescription for, 1422
- Acoumeter, a normal, 34
- Acroparesthesia, 1816
- Actinocutitis from X-rays, 1149
- Actinomycosis, cases of, 291
  - human, 291
  - medical treatment of, 1314
- Adami, J. G., study of burns, 1416
- Adams, F. L., extrauterine pregnancy, 1492
- Addison's disease, 529
  - disease, suprarenal preparations in, 1593
  - disease, suprarenal tablets in, 219
  - disease, treatment of, 801
- Address, Association of American Physicians, 1339
- Address, Iowa State Medical Association, 1493
  - Kentucky State Medical Society, 1725

Word-blindness, 1239
Word-deafness, 1182
Wounds, cutaneous, 527
  incised, 216, 336
  iodoform filling for, 1897
  on shaved head, physician may testify as to, 917
  sodium bicarbonate for dressing, 142
Wright, A. L., surgery of gall-bladder, 1493
Wyeth, J. A., hip-joint amputation, 1361
  J. A., oration on surgery, 1611
  J. A., president-elect, 1629

Wyman, W., sanitation and progress, 609
Wyoming medical news, 1712

X fever of South, 1815
X-ray, 350, 771, 1352
  burns, 692, 1356, 1417
  dermatitis, idiosyncrasy not a factor in, 341
  diagnosis, 690
  elbow fractures and, 777
  in cancer, 348
  in quackery, 577
  lupus vulgaris treated by, 466
  photography, 1209
  pictures, verification of, 1140
  skin lesions of, 1149
  value of, in medicine and *surgery*, 344
X-rays, skin lesions of, 1149
X-rays, enchantment of, by Uranium rays, 1079
  in general practice, 986
  operating under, 1323
  in tuberculosis, 768
  treatment of cancer by, 1415
Xanthoma multiplex, 563
  multiplex, obstructive jaundice with, 592
Xeroderma pigmentosum, 769
Xiphopagus, another, 1186

Yaws, nature of, 1127
Yeast fungus, 66
  in alimentary canal, 411
Yellow fever, 841, 1892
  fever and its transmission, 508, 1040
  fever bacilli, 137
  fever, bacteriology of, 40
  fever, cold baths in, 1745
Yellow fever commission, report of, of Liverpool School of Tropical Medicine, 897
  fever, conveyance of 1191
  fever, eradication of, in Havana, 1185
  fever, etiology of, 431, 446, 461
  fever, experimental, 1414
  fever germ, the, 673
  fever in Port Limon, Costa Rico, 905
  fever in Rio Janeiro, 295
  fever investigation, 679
  fever, mosquito theory of, 347
  fever, negative Diazo—reaction in, 851
  fever, propagation of, 1050
  fever, provisions for eliminating, 613
  fever reports, Port Limon and, 750
  fever, sero-diagnosis of 220
Yohimbin, 768
Yukon, Health on, 515

Zeisler, J., specialties and specialists, 1
Zeit, F. R., uretero-intestinal anastomosis, 206
Zestocausis, atmocausis and 606
Zimmermann, C., light and seating in school, 177
Zinke, E. G., fibrocystic tumor of uterus, 52
Zoologic names, 62
Zoology and medical school of curriculum, 1538
Zoster fever, infectious origin of, 1432
Zymases, importance of, in infant feeding, 475
Zymotic diseases, immunity in, 1036, 1192, 1264

INDEX OF DEPARTMENTS

BOOK NOTICES

Aldrich, F. L. S., Boudoir Companion, 1487

AMERICAN MEDICAL LITERATURE

INDEX OF TITLES

Explanation: This index covers titles and subjects of original articles published in the medical journals of the United States and Canada during the past six months. The titles, and the journals in which they appeared, were published weekly in the Current Medical Literature department, to which references are made. The figures in ( ) refer to the paragraph; the number following, to the page in The Journal. For instance, "Abortion, criminal, (127) 525" refers to page 525 of The Journal, on which is found opposite paragraph 127 the title and name of author, viz., "Criminal abortion. W. D. Stewart." This title is listed under the journal in which the article appeared: The Toledo (O.) Medical and Surgical Reporter for February. For titles of articles in The Journal see General Index.

Abdomen, contusion of, (26) 1275
  contusions of, (16) 1424
  need of thorough examination of, (82) 1660
  penetrating wounds of (19) 1891
  three laparotomies for penetrating wounds of, (139) 688
  trimanual method of percussion for detection of fluids in, (35) 1659
Abdominal diseases, right-side, surgical diagnosis of, (70) 841
  infections, importance of recognition of, (13) 1659
  operations, (50) 1348
  section and drainage in puerperal infection, indications for, (14) 403
  section, preferable technique of closing incision in, (70) 1142
  section, removal of child's head by, (100) 469
  section, some cases of, (84) 992
  surgery, (77) 766, (158) 1348
  surgery, moot questions in, (134, 138) 1143, (41) 991
  surgery, pelvic and, combined operations in (2) 765
  wall, pendulous, resection of, in extreme obesity, (42) 919
Ablation of middle turbinal in cases with symptoms of asthenopia and anomalies of ocular muscles, (20) 1206
Abortion and infanticide from medicolegal standpoint, (104) 1349
  criminal, (127) 525
  medicolegal status of, (85) 1424
Abscess, amebic, of liver, (13) 524
  cerebral, result of chronic suppuration of middle ear, (45) 1276
  cerebellar, (95) 1499
  epityphilitic, (103) 1071
  fecal, (26) 1275
  follicular and periurethral, in male, (143) 1276
  idiopathic, of kidney, (21) 1809
  of brain in infant, (77) 1348
  of liver, (94) 284, (80) 404
  of lung (87) 60
  of sac, (3) 468
  of sphenoidal sinus, (141) 1810
  of testicle, (125) 1425
  otitic extradural, operations for, (101) 919, (115) 1425
  otitic, ; topographic anatomy and operative technique of, (101) 1499
  pelvic, (61) 919
  perinephritic, (109) 525, (143) 992
  peritonsillar, (29) 468
  peritonsillar, suprarenal gland in, (51) 1735
  retro-peritoneal, management of, (29) 1659
  retropharyngeal, (87) 404, (30) 468
  subphrenic (142) 1736
  subphrenic, as complication of appendicitis (19) 991
Abscesses (135) 992, (123) 1499
  cerebral, healing of (73) 1071
  metastatic joint (32) 1206
Abscess, perirectal (63) 211
  treatment of (96) 1735
  tubercular, treatment of (68) 687
Achylia gastrica (20) 210
Acids and bases of urine (42) 1660
Acne, treatment of (85) 1499
Acromegaly, case of (53 and 54) 403, (10) 1275
Actinomycosis hominis (101) 211, (105) 920, (92) 1348
Adenitis, abscess and (87) 404
  cervical, purulent rhinitis as source of infection in (29) 283
  chancroidal, treatment of (94) 841
Adenoid operations, accidents attending, (145) 1810
Adenoids, deformities or defects in development from (27) 1141
Adenoma, mammary and appendectomy, radiographs of (113) 920
Addison's disease (67) 525
Address, Academy of Medicine of Cincinnati (29) 1070
  Albany Medical College (112) 525
  American Gynecological Society (94) 211
  American Medical Association, (7, 11, 15, 27) 1809
  Arapahoe County Medical Society (104) 992
  Atlanta Society of Medicine (143) 598
  before Long Island College Hospital (74) 841
  Cincinnati College of Medicine and Surgery (28) 1586
  Dr. Horsey's (112) 1736
  Ensworth Hospital Medical College (135) 1660
  Fort Wayne College of Medicine (28) 1070
  in memory of R. B. Cole (113) 687
  in ophthalmology (71) 525
  Jackson County Medical Society (67) 135
  Lincoln Club (111) 992
  Medical Convocation (113) 1736
  Medical Society of State of Pennsylvania (74) 60
  Miami Medical College (37) 1735
  Morganfield District Medical Association (83) 1499
  Provincial Board of Health (124) 766
  San Joaquin Valley Medical Society (106) 1276
  Seaboard Medical Association (124) 469
  Toledo Medical Association (126) 525
  University of Tennessee (111) 1142
Adenoid growths of post-pharynx (40) 468, (40) 840, (146) 1277
Adenoids and tonsils, persistence of symptoms after removal of (38) 840
Adenoids, diagnosis and treatment of, (98) 1071
  in adult, pathology of (122) 1499
  pharyngeal, and hypertrophied tonsils (20) 687
  pharyngeal, frequency and sequelæ of (23) 468
Adhesion of soft palate to posterior wall of pharynx (19) 597
Adhesions, old, abdominal section for (96) 469
Adiposis dolorosa, case of (24) 344
Adolescent period, medical treatment during (142) 1661
Adrenal body in broad ligament (95) 211
Adrenalin (111) 1424, (118) 1425
  clinical experiences with (23) 1348
  new hemostatic (66) 1499
Advertising in the profession (1) 1141
Affections, hemorrhagic, of the skin (85) 1207
  lymphatic and portal, following appendicitis (119) 598
Aged, nasal condition observed in (10) 1659
Agglutinins, considerations on nature of (60) 525
Ailments, slight (125) 1276
Ainhum, case of, (69) 1809
Air in digestion (24) 1586
Air-passages, prescription application in many affections of (142) 920
  tuberculous disease of upper (22) 344
  affection of upper, derangement of circulation and digestion in (59) 687
  upper, tubercular disease of (53) 1586
Akouphone and its limitations (22) 1206
Albumin, various rings in Heller's nitric acid test for (88) 135
Albuminous nutrition and nutritious albumin (19) 840
Albuminuria of adolescence and cyclic albuminuria, (61) 1891
  cyclic, (61) 1891
  prognosis of various types of (121) 136
  without manifest organic renal lesions (52) 1348, (162) 1810
Albumosuria in diseases of osseous system, (60) 1891
Alcohol (27) 687
  action of (102) 766
  and tobacco amblyopia in Cuba (123) 1587
  as therapeutic agent (85) 525
  food value of (33) 1424, (16) 1498
  in acute infectious diseases of children (49) 1206
  in carbolic acid burns (8) 1659
  in practice of medicine (140) 1587
  influence of, on muscular work (101) 766
  is it food or poison (100) 766
  physical effect of (124) 1143
Alcoholism (102) 525
  chronic, pathology of (51) 919
  treatment of, (72) 1891
Alexander's operation (128) 1349
Alkaline medication, pharmacology of (87) 345
Alloxuric bodies (43) 1660
Alopecia, hysterical, of eyelids (82) 404
Amblyopia following use of Jamaica ginger, cases of (48) 524
  from use of wood alcohol (141) 1276
  hysteria and (35) 1142
  sympathetic nervous system and, (70) 1809
Ambulances, requisite to increase use of (7) 1070
Ameba coli in relation to Philippine dysentery (13) 686
  coli, observations on (10) 918
American medical centers, neglected clinical opportunities in (31) 135
  medical colleges and their betterment (39) 687
Amenorrhea and emmenagogues (123) 1071
Aminoform, cystitis treated with (113) 1276
Ammonium persulphate, disinfectant and deoderant action of (81) 919, (27) 1424
Amputation above knee under spinal subarachnoidean cocainization (138) 1071
  hip-joint, for tubercular osteomyelitis by Wyeth's bloodless method (111) 469
  of both feet under spinal anesthesia with cocain (9) 686.
  of feet and hands, saving one little finger and part of thumb (22) 210
  stumps, remarks on construction of (33) 524
  supra-vaginal, of uterus (97) 1142
Amyloid kidney (57) 840
Analgesia from spinal subarachnoid cocainization (79) 1660
  hysterical anesthesia and (27) 597
  spinal (131) 598, (14) 1423
Analogies between nervous and electric mechanisms (77) 60
Anastomosis, artificial, of portal and systemic veins (36) 1586
  intestinal (28) 919
  method of performing, in hollow viscera by new instrument (96) 597
  uretero - intestinal, natural (102) 1424
  uretero - intestinal, pathology and bacteriology of (3) 1423, (23) 1586
  vesicosigmoidal (59) 1424
Anatomy, applied (59) 283
  how to teach (125) 920
Anchylostomiasis (63) 1071.
Anematosis, extreme, case of (148) 1143
Anemia in its relation to surgery (82) 345

Anemia of youths and hyperchlorhydria, relations between (131) 136
  pernicious (119) 687
  secondary, treatment of (146) *211*
  simple, extreme case of (19) 1348
  splenic (20) 283, (14) 991
Anesthesia and analgesia, hysterical (27) 597
  by intraspinal injection of cocain (117) 136
  by nitrous oxid gas and ether (95) 1276
  chloroform (138) 1736
  faradic (48) 1735
  general, preliminary and after-treatment of (6) 344
  local, in operation for inguinal hernia (25) 60
  local, some uses of, in genito-urinary work (61) 840
  local, without danger (97) 1207
  medullary (104) 60, (52) 403
  nitrous oxid (64) 1660
  paralysis (13) 1347
  remarks on (26) 1348
  spinal (38) 524, (111) 1660
  spinal, by cataphoresis (2) 1423
  spinal, literature of (34) 468
  spinal, in rectal cases (117) 284
  spinal, physiology of (14) 135
  spinal, with cocain, amputation of both feet under (9) 686
  subarachnoid (91) 135, (99) 284, (71) 468
  and anesthetics (110) 469
Anesthetics, administration of (124) 1207
  deaths from (24) 1424
  deductions from administrations of numerous (99) 766
  facts regarding (47) 135
  selection and administration of (94) 1071
  use of general (68) 1424
  use and abuse of, (23) 1809
Aneurysm, aortic (98) 687, (73 and 101) 1276
  arterio-venous, of retina (125) *1587*
  cirsoid, of ear (110) 211
  excision of, cases of (17) 991
  ligature of innominate for, of right common carotid and subclavian (131) 61
  of ascending aorta (13) 1498
  ruptured traumatic, of femoral artery due to gunshot wound (14) 1206
  thoracic, treated by subcutaneous injections of gelatin (9) 918
  thoracic, (68) 1499
  traumatic popliteal (49) 60
Angeioma cysticum of nose (19) 919
Angina ludovici (16) 60, (83) 1810
  membranous, due to streptococci (7) 1734
  pectoris, death from (99) 1348
  pectoris, neurology of (92) 766
  pectoris, symptomatology of (85) 766
  recrudescence, due to Friedlander's bacillus (4) 59
Angioma of internal jugular vein (114) 687
  venous, of flexor muscles of fingers (16) 1206
Angiosarcoma of choroid (124) 1587
  of skin, multiple (50) 840
Aniline in aural surgery (105) 1349
Animal nature, grosser, brief resume of (87) 1587, (77) 1660
Animals, affected by rabies, long period of incubation in (85) 919
Anisometropia (17) 1586
Ankle-joint disease, treatment of (126) 211
Ankylosis of temporo-maxillary *articulations with osteoclasis* (98) 1142
Ankylostomiasis, thymotal for (15) 765
Ano, fissure in (114) 598
  fistula in (108) 284
Anomalies, rare cardiac (52) 597
Anophthalmus, congenital (69 and 71) 766
Anteflexion, importance of, and its operative treatment (64) 468
Antiseptics, comparison of (55) 1276
  intestinal, with aseptic pads (5) 1347
Antistreptococcic serum, erysipelas treated with (70) 1276
  serum in puerperal sepsis (17) 1424, (14) 1659
  serum, streptococcal infection treated by (44) 1586
Antitoxin and intubation (136) 284, (137) 1071
  diphtheria treated with (10) 60, (87) 135, (60) 1070, (83) 1348
  dosage of (41) 1498
  in diphtheria (31) 1659, (105) 1735
  in prophylaxis of diphtheria (69) 991
  intubation and, in laryngeal diphtheria (132) 1587
  membranous croup treated with (134) 598
  notes on (123) 1660
  treatment of diphtheria, conclusions on (21) 344
Antrum infection (28) 1735
  maxillary, tuning fork as test for diseases of (100) 919
  shall it be opened, in acute empyema of mastoid cells (46) 345
Anuria, non-obstructive, post-operative (38) 919
Anus, imperforate, case of (12) 1586
  paralysis of sphincters of (79) 1424
Aorta, aneurysm of descending portion of arch of (98) 687
  ascending, aneurysm of (13) 1498
Aphasia (69) 135, (60) 1348
  with reference to naming center (10) 135
Apoplexy (125) 345
  and hemiplegia (1) 1659
  cerebellar (21) 1891
Apparatus for modifying cow's milk (20) 919
Appendages, uterine, inflammatory diseases of (139) 211
  uterine, palpation of (114) 1736
Appendectomy (73) 525
Appendicitis (7) 59, (76) 211, (120) 284, (122) 920, (84) 992, (30) 1070, (117) 1349, (36) 1809
  acute, treatment of, (169) 1811
  and diseases of uterine adnexa (93) 1735
  and life insurance (120) 136
  and pelvic diseases (68) 284
  and typhoid (66) 284
  and typhoid, diagnosis between (60) 1660
  at Rhode Island Hospital (65) 1660
  cases of (85) 1660
  chronic (107) 1660
  clinical memoranda relating to (65) 468
  complications after operation *for (80) 1587*
  complications during (65) 283
  conservative treatment of (44) 1348
  delayed operations in (51) 60
  diagnosis of (64) 60, (31) 345
  drainage in (3) 1141
  errors in diagnosis of conditions resembling (79) 1587
  etiology of (63) 60, (123) 1207
  facts about (106) 211
  from medical and surgical point of view (28) 597
  in children (67) 284, (73) 525
  in female (22) 468
  in which worm passed through appendix into peritoneal cavity (48) 468
  interesting cases of (124) 1425
  -is there inherited tendency to, (39) 1809
  latent (161) 1349
  lymphatic and portal infection following (112) 404, (119) 598
  medical treatment of (66) 60
  microscopical pathology of, (111) 1810
  operation during attacks of (69) 60
  operation for, which did not exist (95) 469
  operation in interval of (68) 60
Appendicitis operations, series of, (55) 1809
  perforativa in irreducible right scrotal hernia (12) 1734
  peritoneum and omentum in (56) 525
  prognosis of (65) 60
  practical suggestions in treatment of (119) 1425
  problem of (97) 1348
  question of operation for (2) 283
  relation of, to diseases of uterine appendages (63) 919, (103) 1499
  report of operations for, (57) 1891
  results of operation for (24) 1348
  septic infiltration of abdominal walls following (94) 992
  significance of dulness in (22) 524
  subphrenic abscess as complication of (19) 991
  surgical treatment of (69) 284, (33) 765
  traumatism and (92) 841
  treatment of (72) 525, (137) 1499
  value of leucocyte count in (76) 1348
  when shall we operate in (67) 60
  with unusual complications, cases of (126) 992
Appendix, acute inflammation of, preventive operation in (112) 920
  bowel and, sloughing of (62) 687
  cecum and (107) 992
  gangrene of (58) 1424
  in relation to psoas muscle (81) 1142
  origin and use of (75) 1348
  persistent fetal type of (76) 1276
  vermiformis, congenital form of hernia of (21) 1275
Applicants, after history of, rejected for life insurance (125) 598
Argentamine, external and internal employment of (149) 1143, (113) 1349
Argonin in gonorrhea (113) 211
Aristol in gynic hyperasthesia (100) 1735
Arizona (36) 403
Arm, osteoplastic amputation of, (80) 1810
Arsenical paste, cancer treated with (118) 687
Arterial changes, relation of, to heart (14) 1347
Arteries, muscular action of (13) 1734
Arteriosclerosis in life insurance *examinations, significance of* (116) 1142
  of uterus (54) 468, (12) 1070
Artery, carotid, ligation of, as preliminary to resection of superior maxilla (11) 1206
  femoral, ruptured traumatic, aneurysm of, due to gunshot wound (14) 1206

Convalescence, puerperal (53) 1[illegible]
Convulsions, epileptic (100) 1207
  frequent, apparent cure of (70) 1348
  in children (30) 840
  latent puerperal, after delivery (94) 136
  puerperal, treatment of (136) 766
  with scarlet fever (18) 686
Cornea, dioptric power of (84) 404, (59) 1348
  nutrition of (129) 1587
  optical treatment of conical (79) 135
  uncommon disease of (81) 135
Corning-Bier method (71) 468, (25) 840
Corns (69) 597
Cornu cutaneum auris (1[illegible]
Cough, causes of, in children (100) 992
Coughs, heroin hydrochlorid as remedy in (140) 1071
  suppression and cure of (125) 1349, (144) 1425
Country health officer (100) 525
Cow's milk, apparatus for modifying (20) 919
Coxa vara (43) 765
Coxalgia, cases of (54) 210
Coxitis, retardation of growth for shortening after (10) 403
Craig Colony for epileptics (169) 767
Cranium and insanity, traumatic injuries of (156) 61
Cremation (107) 136
  as life insurance problem (118) 1142
Creosotal in treatment of pneumonia (133) 61
Creosote in pneumonia (20) 1070, *(127) 1736*
Cretinism, acquired, treated with thyroid extract (173) 61, (62) 60
  sporadic, cases of (98) 841
Crime, insanity in its relation to (159) 284
Criminal, insane or, (46) 1891
Criminality (41) 1424
Criminals from standpoint of physician (44) 991
Crime, morphinism and (66) 1424
Croup, apyretic membranous (103) 60
  membranous (133) 284, (134) 598, (138) 992 (141) 1499
Crystalline lens, dislocation of, in immature cataract (29) 60
Culex, biography of, (38) 1891
Curettage of uterus, diagnostic (37) 1659
Curette, abuse of (151) 1143
  adenoid (150) 212
Curettement, uterine (123) 525, (74) 1206
Curvature of spine, cases of (35) 403
  of spine, lateral (7) 210, (31 and 97) 597
  rotary lateral, and Pott's disease of spine (15) 210
Cycling vomiting (54) 1660
Cyst, dermoid, of ovary (7) 524
  dermoid, of scalp (132) 1499
  double intra-ligamentous (99) 469
  hydatid, of tail of pancreas (95) 687
  multilocular renal, surgery of (92) 595
  osseous, of tibia (130) 1736
  ovarian, and suppurating hem*atocele (134) 1349*
  papillomatous, in child (45) 1348, (149) 1349
  parotid (64) 211
  parovarian, in child (123) 211
Cystinuria, case of, ending in recovery (3) 1275
Cystitis (93) 525, (137) 841, (125) 1425, (56) 1735
  auto-inocular (153) 1810
  bacteriology of (72) 597
  chronic, how a country doctor treats (93) 468
  chronic, with surgical kidney (91) 1735
  gonorrheal, in female (22) 283
  in female, simple device for draining bladder in (148) 992
  observations on, with presentation of cystoscope (74) 1142
  treated with aminoform (113) 1276
Cysto-nephroses, septic infections of kidneys and (90) 841
Cystoscope in diagnosis of diseases of genito-urinary tract *(148) 841*
  ureter, new (31) 1586
Cystotomy, method of performing suprapubic (16) 283
  suprapubic (26 and 35) 687, (99) 1276
Cysts, branchial, and fistulæ (8) 403
  dentigenous (148) 211
  dermoid and other, of ovary (77) 1142, (136) 1349
  dermoid, or ovary (59) 1660
  of ovary (53) 468
  ovarian, in colored women (17) 210, (57) 403
Cytotherapy, serotherapy and (43) 1498

Dacryocystitis, (71) 1891
Dammschutz (91) 1348
Dandruff, treatment of (160) 1810
Deaf-mutism, pathology of (119) 1499

Deafness, catarrhal, treatment of, by electrolysis of Eustachian tube (34) 919
  contribution to study of (139) 1736
Death after abdominal operations, causes of (95) 1660
  from drowning (94) 1276

  traumatic injuries of, (48) 1142
Sleep, certain disorders of, (10) 1141
Sleeplessness in heart disease, (45) 1070
Slide lifter and holder, (21) 210
Sloughing, complete, of both nipples, (95) 1207
Smallpox, (42) 283, (111) 766
  and vaccination, (135) 841
  diagnostic sign of, (70) 1586
  epidemics, necessity of coercive methods in suppressing, (162) 767
  hemorrhagic, fatal case of, (125) 992
  history of case of, (67) 1660
  in children, (36) 597
  in Guadalupe County, (130) 1587
  is it, (142) 841
  observations on, (90) 1071
  of present epidemic. (66) 135
  Osborn treatment of. (143) 211
  pathology and antiseptic treatment of, (133) 766
  symptomatology and prophylaxis of, (89) 1071
Smith's fracture of lower end of radius, case and skiagraph of, (17) 840
Sneezing, case of, (84) 1207
Society, a local medical, (120) 404
Sodium bromid in vomiting of pregnancy, (53) 1735
  sulphate, (52) 1735
Soft palate in influenza, appearance of, (27) 1735
Solvent, physiologic, in treatment of pus gases, (33) 210
Sound, localization of, and its bearing on hearing, (21) 1424
South Africa, medical aspects of war in, (115) 992
Spanemia, (103) 597
Specialism in the arts and sciences, (10) 210
  and general practice of medicine, (31) 1891
Specialist and general practitioner, (155) 61
  the, from practitioner's point of view, (74) 404
Spectacle diseases, (105) 992
Spectacles, use and abuse of, (44) 524, (9) 765, (144) 841
Speculum, rectal, improved, (30) 345
Speech, defective, diagnosis and treatment of some functional forms of, (16) 468
Sphenoidal wings, pneumatic sinuses in, (99) 919
Sphincter of iris, rupture of, and of choroid, (94) 1810
Spinal cord, degenerative diseases of, associated with anemia, (31) 210
  cord, diffuse degeneration of, (50) 468, (109) 766
  puncture, use of cocain in, (40) 765
Spine, curvature of, cases of, (35) 403
  hyperextension of, in treatment of paralysis of Pott's disease, (51) 283
  primary sarcoma of. (116) 1425
  rigidity of, (34) 1735
  rotary lateral curvature of, (151) 920
  treatment of tuberculosis of, (66) 525
Spirit and drug takers, facts of responsibility in, (27) 1206
Spleen and kidney, laceration of, (81) 1810
  enlargement of, (20) 283
  in infancy, chronic enlargement of, (60) 60
  spontaneous rupture of, (10) 1498
  surgery of, (73) 1586
Splenectomy, case of, (76) 404
  report of successful, (146) 1349
Splenomegaly, primary, (47) 1276
Spondylitis. tubercular, indications for, renewal of plaster-of-paris jacket in. (43) 1276
Spondylolisthesis, (102) 469
Sponges and other foreign bodies, fate of, in peritoneum, (117) 841
Spongifying of labyrinth, (88) 468
Spray in gynecologic diseases, (71) 1142
Sputum examinations, value of, to general practitioner, (7) 686
Squint, convergent, (44) 1275
  latent, or esophoria, (25) 1424
  plea for early recognition of, in children. (56) 1142
Stab wounds of abdomen, (55) 1735
Stammerers, male, preponderance of, over female, (9) 1206
Stammering, how to prevent, (16) 1070
Standard of preliminary requirements in practice of medicine, how to make a uniform, (78) 1424
Staphylococci, infection with, (11) 1347
Starch, iodized, as therapeutic agent, (135) 211
Starvations, two, (43) 1424
State association, unity of action in, (55) 1586
  hospital and sanitarium work, outlook for young physician in, (36) 1348
  hospital, relations of private to, (116) 1736
  hospitals for insane, results of experience in, (52) 919
  hygiene, report of, (147) 1143
State medicine, (45) 1735
  sanatoria for consumptives, (97) 1276
Stave of thumb, skiagraph of Bennett's fracture of, (16) 840
Steel removed from vitreous, (97) 1810
Stenosis, congenital hypertrophic, of pylorus, (35) 597
  laryngeal, (78) 991
  mitral, (115) 1142
Stereognosis and allied conditions, (111) 841
Sterility, (74) 284
  primary, reflections concerning, (44) 766
Sternum, gumma of, (28) 1141
Sternutation, case of, (105) 1660
Stethophonometry, (31) 597
Stille, A., sketch of, (59) 403
Stimulation, nutrition and, (102) 1499
Stirpiculture, (163) 212
Stomach and bowels, dilatation of, (74) 525
  bacteriology of, (52) 210
  cancer of, surgical treatment of, (132) 469
  carcinoma of posterior wall of, (25) 765
  chronic ulcer of, (25) 1659
  clinical notes on, (67) 345
  common diseases of, and their surgical treatment, (92) 284
  contents, examination of, with respect to fermentation products, (81) 404
  diseases, chemical methods in diagnosis of, (132) 346
  diseases of, (44) 60, (38) 468, (36) 840, (39) 1586, (136) 1736
  hair-cast of, removed by laparotomy, (1) 596
  perforating ulcer of the posterior wall of the, (95) 841
  physical examination of, (7) 991
  prognosis and treatment of dilatation of, (108) 404
  secretory neurosis of, (42) 403, (119) 525
  (see cancer, ulcer)
  surgery of, (6) 403
Stone in bladder, choice of operation for, (89) 841
  in kidney, diagnosis of, (136) 61, (39) 919
  to cut or crush, in urinary bladder, (38) 991, (139) 1143
  urinary, probable mode of formation of, (48) 210, (33) 345, (36) 468
Stones, impacted, choledochotomy for removal of, (62) 1071
  renal and vesical, note on color, of, relative to their detection by radiography, (29) 687
Strabismus, management of, (30) 597
Strain, muscular atrophy following, (99) 345
Strangulation, description of hitherto unrecognized cause and seat of, (31) 1275
Streams, bacterial self-purification of, (29) 135
Streptococcal infection treated by antistreptococcus serum, (44) 1586
Streptococci, prevalence of, in cow's milk, (20) 1275
Streptococcus bronchitis in influenza, (24) 1735
  in gynecology, (110) 1660
Stress, intrauterine periods of, (84) 1348, (43) 1735
Stricture, cicatricial, of pharynx, cured by plastic operation, (93) 597
  gonorrheal, of urethra, treatment of, (8) 1586
  of rectum, treatment of, (35) 210
  urethral, treatment of, by electrolysis, (140) 992
Stridor of infants, causation of congenital, (41) 345
Strychnin, (157) 1810
Stylohyoid arch, osseous, (81) 1499
Subarachnoidean injection where general anesthesia could not be carried out, (156) 1349
Subglottic growths, (13) 918
Sulphates, urinary, and fecal fat in diagnosis of pancreatic disease, estimation of, (49) 1276
Stump, double conicle, following of amputation of both arms in utero, (113) 469
Sugar and the doctor, (101) 1587
  in urine, some fallacies in testing for, (55) 60
Sulphate of magnesia, practical experience with, (92) 687
Sulphates, ethereal, indican and, (43) 135
Sulphur, (78) 345
  cream, therapeutic notes on, (51) 1891
  and its derivatives, (57) 1070
  compounds in chills, (116) 136
Superacidity, hydrochloric, notes on, (160) 1349
Superheated air in otitis media, (3) 1734
Suppuration, nasal, (117) 1207
  of middle ear, cerebral abscess result of, (45) 1276
  pelvic, conservatism in, (97) 766
Suprarenal capsule, (15) 1141
  capsule, aqueous extract of, (21) 524
  capsule, hemorrhage into, (97) 1071
  capsule in heart diseases, (4) 1423, (26) 1586
  capsule, use of, in hemoptysis, (25) 919
  extract in diseases of eye, (138) 920
  extract in diseases of middle ear, (137) 284
  gland, aqueous extract of, in persistent epistaxis, (5) 765
  gland, efficiency of, (39) 135
  gland in peritonsillar abscess, (51) 1735
  glands, blood-pressure-raising principle of, (137) 1425
  liquid, use of, with chloretone, (156) 284
  liquid with chloretone in rhinology, (100) 1142
  liquid with chloretone, use of, (156) 284
Supra-scapular artery, fracture of clavicle, resulting in rupture of, (27) 60
Superaciditas chlorhydrica, (18) 1891
Surgeon, what the law requires of the, (88) 284
Surgeons, eastern, reply to criticism on methods of, (97) 469
Surgery and medicine of other times, (39) 403
  as a specialty, (96) 1348
  aseptic minor, (62) 840
  conservatism in, (39) 765
  in country practice, (130) 1499
  intestinal, (164) 212
Surgery, intestinal, cases of, (159) 61
  intestinal, in middle ages, (130) 136
  lectures on, (66) 1735
  of 19th century, (104) 284, (31) 991, (94) 1660
  phenomenal century of, (127) 841
  regional minor, (128) 61, (123) 284, (136) 688, (90) 1207
  relation of student and recent graduate to field of, (32) 1348
  science and art of, (110) 1735
  world debt to, (124) 61
Surgical cases, preparation and after-care of, (92) 919
  cases, report of few, (149) 767
  clinic, (85) 687
  dressing, modern, (120) 1587
Susceptibility to disease and physical development in college women, (12) 1275
Suspicion, morbid, degeneracy stigmata as basis of, (46) 687
Suture, intestinal, all knots inside, (85) 1348
  removable buried, for abdominal incision, (60) 283
  secondary, (16) 1734
Sweet Chalybeate Springs, Va., (47) 1809
Symblepharon operation, (127) 1587
Sympathetic ophthalmia, (120) 1276
Symphysis pubis, rupture of, (52) 1660
  pubis, traumatic separation of, (67) 1891

Synchronous amputation for gangrene, (9) 1890
Syndactylism, (137) 1661
Syncytioma malignum with metastases in vagina, (104) 469
Synovitis of knee, (102) 284
Syphilis, acquired and inherited, (127) 136
  and associated affections, (80) 525
  cerebral, paresis and, (83) 1587
  constitutional treatment of, (123) 920
  discussion of Dr. Foster's questions on, (119) 1810
  elimination and curability of, (56) 1586
  hereditary, gummous tumor in larynx due to, (128) 1499
  hereditary, importance of early diagnosis in, (118) 284
  in the well-to-do, (35) 1498
  malignant, cured by Zittmann's decoction, (48) 840
  nasal, (38) 765
  nine questions on, answered (108) 992
  nitrite treatment in, (11) 135
  of nervous system, (24) 1498
  of nose and throat, *(150) 1810*
  of testicle, unusual case of, (114) 469
  othematoma in, (82) 525
  Pre-Columbian, leprosy and, (118) 598
  refractory, with report of case resistent to specific treatment, (54) 597
  treatment of, (174, 176) 767
  treatment of, at Hot Springs, Ark., (24) 403
Syphilitic disease of facial bone, (75) 1276
Syringe and how to use it, (130) 469
  shielded piston, for urethral and vesical irritation, (6) 1206

Tabes dorsalis, modern treatment of, (109) 1424
  dorsalis, recognition of, (31) 1735
  dorsalis, study of cases of, (47) 1586
Tape-worm, quick removal of, (149) 841
Tax, special license, (53) 60, (148) 284

  surgical complications of, (84) 1587
  surgical intervention for intestinal perforation in, (74) 1586
  sustaining treatment of, (22) 687
  symptomatology and diagnosis of, (80) 60
  [illegible] 212
  [illegible] of,
  theory and therapy of, (141) 767
  thermol in, (66) 687
  treated by Woodbridge method, (52) 1809
  treatment of, (82) 60, (26) 135, (137) 211
  treatment of heart in, (8) 918
  ulcer, perforation of, without fecal extravasation, (23) 60
  up-to-date treatment of, (100) 687
  urines, disinfection of, (13) 283
  Widal reaction in, (27, 28) 1498
Tyrell's operation of drilling, (1) 524

Ulcer, corneal, following advancement operation on external rectus muscle, (83) 404
  duodenal, in infant, (69) 1348
  gastric, (139) 1425, (93) 1810
  gastric, cases of, (7) 344
  gastric, surgery of, (111) 1587
  gastric, symptoms, prognosis and treatment of, (117) 211
  gastric, surgical treatment of, (20) 1809
  gastric, treatment of, (141) 1349
  of the placenta, (52) 1586
  of stomach, pathology of, (110) 1587
  of stomach, treatment of, (112) 1587
  perforating duodenal, with subphrenic abscess, (19) 135
  perforating gastric, (6) 210
  perforating, of posterior wall of stomach, (95) 841
  perforating, of stomach, (14) 596
  serpiginous, of cornea, (161) 212
  vesical, rational treatment of, (86) 60
Ulceration, acute gastric, (3) 840
Ulcerations, erosions and, of triangular cartilage of septum, (98) 1276
Ulcers, chronic, (140) 1661
  gastric and duodenal, surgical treatment of hemorrhage from, (125) 766
  wounds and, suggestion on treatment of, (37) 345
Ulna, fracture of, incision in treatment of, (59) 919
Ulcus rodens corneæ, (64) 1142
Umillian murder, the, (23) 1275
Unguentum Crede, therapeutic use of, (103) 687
University of Michigan, historical sketch of, (31) 1275
  of Pennsylvania, medical department of, (13) 1423
Uranalysis, (44) 403
Ureine, facts regarding, (30) 765
  is there such a constituent as, (87) 1348
Uremia from suppression of urine, (120) 1143
  treated with intravenous saline solution, (134) 1276
Ureter, double, (41) 283, (101) 469
  results of ligation of one, (117) 687
  traumatic injuries of, (111) 284
Ureter, vesical implantation of, by Dudley's forceps method, (20) 403
Ureteral surgery, four cases of, (108) 1587
Ureterolithotomy, transperitoneal, located by X-ray, (145) 841
Ureters, calculous disease of, (12) 60
Urethra, female, melanosarcoma of, (170) 1349
  female, new formation of, (54) 766
  curetting, in treatment of, chronic posterior urethritis, (99) 841
  fibromyoma of, (56) 468
  foreign body in, (7) 596
  traumatic stricture of, (129) 284
  wound of, (125) 1425
Urethral discharge, chronic, due to seminal vesiculitis, (118) 1587
Urethritis, acute gonorrheal posterior, treatment of, (9) 1586
  complications of specific, (62) 135
  gonorrheal, (128) 992
  in male, treatment of, (132) 1207
  microscopic technique in relation to diagnosis of, (149) 61
  non-specific, (125) 211
  persistent, pseudo-phosphaturia as cause of, (88) 841
  specific, (151) 767
  Urethrotomy, external perineal, after treatment of, (96) 1424
  external, report of, (71) 991
Urethrotomy, external, modication of Cock's method of, (52) 1891
Uric acid and pregnancy, (107) 404
  acid, conditions due to excess of, (93) 60
  acid, genesis of, (111) 1499
  acid lesions, oxygen treatment of, (101) 404
  acid lesions, so-called, some phases in treatment of, (70) 345
  diathesis, investigation on, (123) 992, (74) 1735
Urinary system, abnormalities of, (70) 468
  tract, bacterial infection of, (46) 1660
Urine, acids and bases of, (42) 1660
  blood in, as a symptom, (5) 840
  in bearing to life assurance, (71) 1735
  of horse in pneumonia, (147) 598
  semeiology, (47) 1206
  some errors in examination of, (32) 1275
  suppression of, as complication in dysentery, (153) 767
  toxicity of normal (30) 135
Urotropin, curative and prophylactic action of, (125) 1071
Urticaria, (90) 992
Uterine appendages, palpation and, (56) 991
Uterus bicornis, dystocia from, with contracted pelvis, (96) 687
  bilocularis or uterus septus, (65) 345
  bicornis, pregnancy in, (105) 1207
  bicornis unicollis, (39) 1659
  blood and nerve supply of, (109) 1735
  cancer of, (87) 992, (103) 1424
  diagnostic curettage of, (37) 1659
  displacements of, operative procedures in, (72) 1348
  duplex, pregnancy in accessory horn in, (66) 1071
  fundus of, malignant disease affecting, (122) 1736
  hyperesthesia of, during pregnancy, (89) 1348
  in labor, re-expansion of, (12) 283
  inverted, twenty-one years duration, (86) 687
  irreducible, incarcerated retroflexed gravid, (105) 766
  malignant diseases of, (110) 1276
  method of removing and preparing portions of tissue from, for diagnostic purposes, (97) 1424
Uterus, osteofibromyoma of, (101) 1424
  posterior displacement of, (52) 60, (79) 211, (152) 212
  pregnant, removal of, for infected placenta previa centralis, (109) 1071
  retrodisplacements of, (53) 210
  retrodisplacements of, operative procedures in, (74) 766, (90) 919
  retroversion of, (60) 991
  sarcoma of, (91) 597
  (see curettement, cancer, tumors)
  spontaneous rupture of, (80) 1071
  subinvolution of, (72) 1499
  treatment of displacements of, with adhesions (98) 1424
  treatment of inflammatory diseases of by irrigation, (82) 211
  treatment of retrodisplacements of, (153) 284
Uvula, superimposed, (2) 59
  pulsation of, in aortic insufficiency, (5) 1890

Vacation schools, physicians' influence in, (101) 60
Vaccin virus, method of preparation of, (27) 1070
  virus, undescribed reaction following inoculation of, (6) 1659
Vaccinal eruptions, (137) 1736
Vaccination, (26) 1070, (101) 1810
  accidental, (110) 525
  acute infective endocarditis following, (13) 60
  aseptic, importance of, (24) 1141
  bad effects following, (139) 1276
  in Alabama, (135) 1276
  proofs that, prevents and mitigates smallpox, (74) 1276
Vaccine, aseptic, and variola, (139) 841
Vaginal ablations, analysis of, (28) 1424
  ablations in pelvic inflammation and uterine fibroid degeneration, (1) 1347
  operation, indications and limitations of, in pelvic diseases in women, (39) 1206
Valescus De Tarenta, life and writings of, (63) 1809
Vapo-cresolene, poisoning by, (122) 61
Varicella in adults, (7) 1423
  in utero, apparent case of, (133) 1660
Varicocele, (114) 136
  of broad ligament, (56) 1660
  radical cure of, (57) 1735
Varicose veins, operative treatment of, (9) 135
Variola, (135, 139) 61, (102) 841
Vascular disease to heart disease, relation of, (27) 1586
Vases, Peruvian, explanation of, (82) 284
Vasodilators in cardiovascular disease, need of greater conservatism in use of, (12) 1498
Vegetations, intestinal, (26) 991
Vein, internal jugular, angioma of, (114) 687
Vena cava inferior, thrombosis of, (53) 1499
Venereal diseases, dangers of, (141) 211
  diseases, ethics of, (102) 1348
  diseases, prophylaxis of, (9) 1141
Ventricle, left, hypertrophy of, in plain stenosis of mitral, (132) 992
Ventrofixation, (103) 1276
Ventro-suspension, pregnancy following, (71) 404
Veratrum viride, (12) 765, (22) 1070, (32) 1586
Vermiform appendix, how to deal with, (14) 1275
Version, (84) 525, (10) 1423
  cephalic, (85) 284
Vertex, management of arrested posterior positions of, (140) 1425
  presentation in fourth position (107) 766
Vertigo, (13) 991
Vesical function, results following cure of defects of, (91) 1071

Vesicles, seminal in gonorrhea, (28) 524
Vesiculæ seminales, tuberculosis of, (64) 525
Vesiculitis, chronic, with reference to technique of stripping, (106) 404
  subacute and chronic seminal, (39) 345
  chronic seminal, (23) 1891
Vibrissæ of mammals, (55) 345
Virginia, medical laws of, (48) 60
  penitentiary, insanitary condition of, (51) 1348
Viscera, complete transposition of, (20) 765
Vision, amount of injury to earning capacity from partial or complete loss of, (80) 135
Visiting the sick, (132) 1143
Vital statistics, practical use of, (18) 135
Vitreous, removal of steel from, (97) 1810
Vivisection, is it useful, (47) 468
Vocal cords, papilloma of, (109) 597
Volvulus and intussusception of Meckel's diverticulum, (23) 1424
Vomiting, apparent periodical, (82) 1587
  nausea and, following anesthesia, (48) 597
  pernicious, of pregnancy, (35) 283
  recurrent, of nervous origin, (16) 1348
Vortex, occipito-posterior position of, (96) 211
War, surgeon in, (114) 284
Warren, J. C., discussion of paper of, (70) 991
Warts, senile, transformation of, into carcinoma, cases illustrating, (25) 687
Water, (126) 345
  analysis, (132) 920
  purification, (113) 1499
  supply, sanitation and, (93) 841
Watson collection, gift of the, (68) 211
Weak back, nature and treatment of, (93) 1660
  heart, cases of, (90) 1735
Wesley, John, as a physician, (31) 919
Western Texas, climatic conditions of, and tuberculosis, (117) 920
What shall the harvest be, (84) 1424
Wheal type, syphilitic lesions of, (81) 525
Wheeling for health, (119) 1143
Where do we stand, (129) 841
Whey-cream modifications in infant feeding, (7) 468
Whistle, a, in esophagus, (22) 919
Whooping-cough, treatment of, (11) 283
Widal reaction in infancy and childhood, value of, (42) 1586
  test, contribution to technic of, (3) 918
Widal's reaction, plea for uniformity of technique in, (22) 1586
Will, the, in health and disease, (127) 992
Wilson's *criticism, reply to,* (75) 919
Women in medicine in Germany, (39) 468
  role of infections in diseases of, (107) 1810
  routine examination of, following confinement, (102) 992
  sexual phases and crises of, (123) 136
Wound, perforating, of eyeball, (88) 1348
Wounds and ulcers, suggestion on treatment of, (37) 345
  cutaneous, closure of, without suture, (17) 524
  dissection and operation, etiology of, (118) 136
  incised, treatment of, (127) 1143
  new method of coapting superficial incised, (121) 211
Wrists, congenital deformity of, (16) 1275
Write, how to, well, (119) 992
Wyeth's bloodless method in osteomyelitis, (111) 469

Xeroderma pigmentosum, (41) 765
Xeroform, enteritis with, treatment of, (144) 920
  "X" fever of the South, (168) 1811
X-light, notes on, (29) 1348
X-ray, bullet in hip-joint located by, (146) 841
  diagnosis, (54) 135, (118) 525
X-ray, gall-stones under, (128) 688
  in fractures and dislocations, (69) 1735
  in medicine and surgery, (59) 1735
  in surgery, (87) 1810
  photography, (26) 1206
  plate, development of, (126) 688
  tissue injury by, and result of prosecution in court, (129) 688
  value of, to general practitioner, (87) 1207
X-rays, (138) 766
  electrochemical action of, in tuberculosis, (24) 765
  review of literature on, (1) 1206

Yeast fungus, conditions characterized by, (134) 61
Yellow fever, correlation of facts in propagation of, (14) 1141
  fever, drinking-water and the mosquito as cause of, (10[illegible] 469
  fever in houses, note on spread of, (13) 1891
  fever, mosquito theory of transmission of, (16) 344
  fever, period of incubation of, (1) 840
  fever, progress made in 19th century in study and propagation of, (19) 524
Yohimbin and its salts, (14) 765

Zoologic names, use and abuse of, by physicians, (14) 60

AMERICAN MEDICAL LITERATURE

INDEX OF AUTHORS

(This Index includes the names of the authors of the articles which have appeared in this journal, as well as of those listed under Current Medical Literature.)

The * preceding the page reference indicates that the article appeared in full in The Journal.

Abbe, R., (28) 597, (97) 1348
Abbott, E. G., (3) 1206
Abbott, S. W., (126) 766, (117 1142
Abel, J. J., (63) 1206
Abell, I., (45) 468, (37) 1070
Abrahams, R., (4) 524
Abrams, A., (5) 210, (35) 345, (21) 597, (30) 687, (8) 918
Abston, J. T., (151) 841
Abt, I. A., (78) 991, *1166
Acker, G. N., (54) 1660
Adair, J. M., (46) 1498
Adam, G., (133) 136
Adami, J. G., (11) 1734
Adams, A. L., (120) 1276
Adams, A. V., (33) 524
Adams, C., (159) 284
Adams, E., (35) 524
Adams, J. H., (43) 468
Adams, S. S., (36) 60, (122) 61, (53) 1660
Adams, Z. B., (32) 210
Adriance, V., (50) 1276, (69) 1348
Aftel, G., (76) 1499
Agar, L. C., (54) 1206
Agramonte, A., *431
Ahlborn, M. B., (105) 687
Aiken, J. M., (81) 1660

The Journal of the American Medical Association

Vol. XXXVI. CHICAGO, ILLINOIS, JANUARY 5, 1901. No. 1.

Address.

SPECIALTIES AND SPECIALISTS.*

JOSEPH ZEISLER, M.D.
Professor of Skin and Venereal Diseases.
CHICAGO.

Specialism is a significant feature of our times and by no means confined to medicine. Few eminent lawyers undertake to practice all phases of jurisprudence; many devote their efforts to one distinct department only. Thus we have the criminal, the patent, the real-estate, the probate, the mercantile, the corporation, and, lastly, but not of the least interest to some physicians, the collection lawyer. Few painters have achieved world-wide fame unless by constant application to a single purpose. Rosa Bonheur and Verboeckhoven have never tired of depicting animals, the Barbizon school has revealed to us the beauties of rural life, Mezdag is known only by his marine pictures, Israel by his frugal interiors, Meissonier by his war scenes, Lenbach and Whistler by their realistic portraits, our own Innes by his inimitable landscapes. In all domains of mental energy, in commerce and the industries, we find specialties. Who can wonder then that the phenomenal development of medicine during the past fifty years has of necessity led, not to its division into as many independent departments as there are different organs in the body, but—comparing it to a tree—to a healthy and strong development of all its branches to a degree where some of them, while still drawing their life-blood from the same old roots, and while still firmly attached to the same old trunk, have grown to imposing dimensions. Specialties in medicine are, therefore, not the arbitrary, capricious, artificial products of the respective specialists, but the legitimate result of increased medical knowledge, the inevitable and irrepressible consequence of evolution.

Some specialties have long ago reached their age of maturity and few of you will question their standing and title to-day. In the majority of good medical schools, here and abroad, there have been for a long time separate chairs of ophthalmology and otology, gynecology, laryngology, neurology and psychiatry, pediatrics and dermatology, although examinations in all these branches were not always obligatory for obtaining a degree. Advisedly I do not mention obstetrics here, for a long time recognized by a special chair, for it is rare that practice is confined to it exclusively; nor would it be proper to call surgery a specialty. Of more recent date are the specialties of rhinology, orthopedic surgery, and genito-urinary surgery. In practice, but hardly in the regular degree-conferring colleges, we have proctology, as it lately has been baptized—not to mention the title of orificial surgery—gastrology, and abdominal surgery. To those of you who in the near future may find an overcrowded state of affairs in most of the specialties just enumerated, I would suggest a few good openings, as follows: Glossology (diseases of the tongue), hepatology (diseases of the liver), nephrology, splenology, pancreatology, thyroidology, onychology (diseases of the nails), etc., ad libitum. The general public, of course, is constantly creating all sorts of specialists, as for instance the specialist for rheumatism, for appendicitis, for intubation, the fever and the catarrh specialists; the complexion and the hair specialist, and so on. Let us not forget one important species, the specialist for everything—the man who never turns anybody from his door, who treats anything and everybody. As varieties of this marvelous category, we might mention the osteopath, the "Christian scientist," the Dowieite, vitopath, hydropath, electropath, and other charlatans.

In view of the tremendous array of specialties just alluded to, some of you might well ask if there is anything left for the general practitioner. To this I would answer: everything. Not only in the smaller communities, but even in the larger centers of population, the historic style of the well-trained, good, all-around, general practitioner will and must remain the backbone, or as my friend Patrick would call it, "the solid Muldoon," of the medical profession, and with the continued improvement in our colleges, this type should attain the highest order of perfection. The general practitioner ought never to collide with the *true* specialist, who, rather than antagonize him, should be his ally in times of need, clearing up a doubtful diagnosis, mapping out a successful line of treatment in difficult cases, always ready to support, never willing to supplant him. The general practitioner will always keep the management of acute diseases, and should be the trusted medical counselor of the household in everything pertaining to hygiene, sanitation, development of children, etc. He will attend to all normal confinements, but will be glad to have his responsibility shared by the expert obstetrician in cases of placenta previa, or face presentation. He will treat the majority of eye affections, but will leave cataract extraction and refined ophthalmoscopic diagnosis to the trained oculist. He will manage all sorts of throat troubles, be prepared for the use of antitoxin against diphtheria, be even ready to perform tracheotomy when emergency arises, but leave intralaryngeal operations and intubations to the skilled laryngologist. And so in all other departments of medicine. But the busy general practitioner will find little time for scientific research work and be content to watch the progress of medicine as an interested and intelligent observer. The bulk of the real work in the science and art of medicine has for years been and will always be done by the pathologist and the clinician respectively, which includes the specialist. And by work I do not mean the writing of journal articles, or the compilation of text-books, but investigation by means of microscope, chemical analysis, animal experimentation and methodical clinical observation on large hospital material, and the publication of such work in appropriate scientific form. Herein I see before everything else, if there is at all need of it, a vindication of the specialties, which are too often unjustly arraigned and held to account for the doings and vagaries of their would-be votaries. The specialties are all right. The specialists are only too often all wrong. The rush to the specialties during the last two decades, particularly in the large cities, has been so impetuous that it naturally resulted in the establishment of a class of mediocre specialists, who often bring discredit on the whole institution of specialism. I have no hesitation in saying that we have too many specialists, but not enough good ones.

---

* Address delivered at the Opening Exercises of Northwestern University Medical School, Oct. 2, 1900.

What are the criteria of the true, the ideal specialist? He should be a man with an excellent general preliminary education. This should even include a knowledge of the more important modern languages, an indispensable accomplishment for one who must follow the international medical literature of to-day. He should have had a broad, comprehensive medical training in college and hospital, particularly in pathology. In addition to this, he should have devoted, according to the line of work selected, from two to four years to his special studies, comprising clinical, literary and laboratory work. He should never lose the intimate contact with general medicine, and no matter how small the field of his special labors may be, he should always remain a physician. The true specialist will never become narrow, and I may later on have occasion to illustrate of at least one specialty the many bonds of union by which it is inseparably tied to general medicine. The true specialist can never afford to stop working scientifically. The continued wave of progress in medicine must be closely followed by him, lest he remain behind, and particularly if he should be a teacher we must expect him to be always at the front. In his practice the true specialist should before all be a reliable diagnostician. Acquaintance with the commoner diseases of any organ may safely be expected of any well-trained and fairly experienced general physician. But we have a right to demand from the specialist thorough and easy familiarity with rare and exotic affections also; in other words, in his rôle as a consultant, he should be an expert. Likewise, should he be fully at home in all therapeutic methods and measures pertaining to his specialty. I think it is perfectly fair to insist that a specialist should confine his practice strictly to his chosen department; and yet it is exceedingly difficult to avoid occasional—at least apparent—conflict with other fields. The neurologist finds himself daily confronted with cases requiring the fullest knowledge of the pathology and treatment of syphilis; the syphilographer again must as often be prepared to meet in his patients, nose and throat, eye and nerve disturbances. The throat specialist will find many of his cases to be complicated by bronchial and lung affections, and the oculist may trace many eye troubles to rheumatism, diabetes or other systemic derangements which call for his interference. In all such cases the specialist must show that he has not ceased to be a physician; he should not degrade himself to a mere tool in the hands of his professional constituents. Tact and judgment will, however, easily keep him from treading on the general practitioner's toes.

Shall I attempt to characterize the would-be, the poor or mediocre specialist? An ungrateful, perhaps an ungracious task. Look around you and see the man who is ever ready to present you his card whereon is inscribed "Practice limited to such and such diseases," who "makes a specialty" of this or that—a disgusting expression to me, by the way—who constantly talks to his friends of his cases and the increase of his income; who appears before medical societies to parade with his poorly observed and often misinterpreted cases; who uses every opportunity at such gatherings to get up and talk for no other purpose than to let his audience know that he, too, has seen cases of exactly the nature that the essayist has described, but that in his hands the drug recommended has been of no value, while a formula of his own or a specially devised instrument, which he forgets to describe, have uniformly proved successful; who, with a lot of others of the same genus, but engaged in different departments, forms a sort of a trust for the exchange of cases; and who often enough, let us be frank, holds out all sorts of inducements to general practitioners for the transfer of special cases; to whom his specialty is indeed naught but a milk cow. Such a man probably enters medical college with a firm determination of eventually "making a 'specialty" of a certain class of diseases. While in college he considers everything which is not directly related to his prospective special field, as irrelevant, gets through his medical course easily, about well enough to barely pass his examinations without being plucked. His sheepskin still damp from the signature of the faculty members, he at once goes abroad for special studies in Paris, London, Vienna. These studies are largely devoted to a minute investigation of the most famous cafés, restaurants, theaters and other places of amusement; a few special courses by privatdocents or assistants, given in a poorly understood foreign language, are however, usually taken along, by the way, as it were. Six or twelve months later, this perfect, newly-made specialist arrives home, where his friends have already been prepared by numerous letters of his wonderful attainments abroad, armed with instruments of the latest pattern, declaiming about the very most recent methods of treatment which he is now the only possessor of, and superciliously sneering at the old fogyish Dr. X, whose competitor he starts out to become. Soon enough he succeeds in buying a professorship in the Æsculapian College for Advanced Clinical Medicine, and what seems most remarkable, many members of the profession open their arms to that sort of medical luminary and shower patronage on him. Even soap bubbles rise up; for a time, at least. Do not consider these remarks as exaggerated or slanderous, but take them, I mean you students, as a timely warning. If you, freshmen, have come here with a specialistic bee buzzing in your ears, kill it at once. If you develop during your college studies a special inclination toward some particular branch of medicine, cultivate it as much as you may, without, however, neglecting any other work. Build a strong foundation for your future by earnest devotion to the fundamental studies, anatomy, physiology, chemistry, pharmacology, and lastly, but most important, pathology. You can never build this foundation too massive. Add as the next story of the structure, as it were, the principles of medicine and surgery. Then, if you choose, you may undertake to erect your specialty on the top floor. But this last part of your training for any chosen specialty can not be gotten in a regular medical college, and should not be expected from it. The teaching staff of a high-grade medical school nowadays must, of course, contain quite a number of specialists. You would not be willing to have the most excellent general practitioner lecture to you on neurology, eye diseases, or laryngology. But your teacher of any specialty, if he realizes his position and appreciates your wants, will, with wise discretion, pick out for your instruction from the bewildering mass of material at hand, those subjects which you are most likely to meet in your future daily work. He will treat exhaustively the more common affections, mention without going into technical details the chief features of the rarer diseases, always maintaining the contact with general pathology, always pointing out the relationship to general medicine and surgery. Taught in this way, the study of the specialties in the college will help to broaden you, rather than to detract from your general medical education.

The step into a specialty may be made in various ways. The opinion frequently voiced that in order to become a good specialist one should have spent from five to ten years in general practice is justified in many respects. At the same time it will easily be admitted that two-years' work in a large hospital, going from one service to another, far outweighs the experience acquired in the former. Work in a hospital is, as a rule, more apt to be of a high scientific order, while busy general practice often leads to routine and from its very nature, the constant strain on mind and body unfits its follower for hard scientific work in one particular line. In what manner attendance on hundreds of cases of labor, pneumonia or typhoid fever can benefit the future ophthalmologist or dermatologist I fail to see. I can comprehend the value and am glad to admit the desirability of general practice as a stepping-stone for the neurologist or gynecologist; but the aforementioned opinion is altogether too sweeping when applied to all specialties. I would put much less emphasis on general practice, but much more on ge[illegible] as the essential basic element for all [illegible] real and ideal school for the specialist must be a large clinical material in hospital and dispensary work, with its attached scientific laboratories, under the direction of an experienced master. The man who, without such schooling, dashes into a specialty is likely to use his private patients as a material for his studies—a somewhat questionable procedure. As I said before, it is this kind of would-be specialists who, by their blunders in the first years of their practice, bring discredit on the whole institution. It is this kind of specialists who evoke such bitter criticism as could be heard in that famous discussion before the Chicago Medical Society about two and a half years ago. Some of our most representative men aired their feelings against the prevailing style of specialism then and there, and while most of what was said could easily meet with the heartiest approval of the unbiased hearer, a good deal was harsh and unjust. Listen to a few of those statements: "And yet one finds specialists of the ear who do not treat diseases of the postnasal space and pharynx. Specialists of diseases of the skin whose knowledge of the digestive and excretory organs is limited." And so, in turn, every specialty is taken to account. Further on the same speaker says, referring to autointoxication, malassimilation, etc.: "The above-named conditions give the dermatologist an opportunity to write volumes on skin eruptions with a nomenclature horrifying in degree." Another speaker evidently intent at being humorous said: "Many specialties have but a narrow basis to build on; they are shaped like an inverted pyramid. Some have been built on an instrument or appliance; others on a nomenclature. Gynecology on the speculum; nose and throat on the laryngoscope; genito-urinary on the endoscope and cystoscope; orthopedic surgery on the tenetome and plaster of paris; dermatology on a nomenclature; nervous diseases on electricity; otology on the otoscope and Politzer's air bag."

I must leave it to those representing other branches of medicine to speak for themselves. But I may be permitted to use this opportunity, though somewhat late, to show the injustice of those hits made at dermatology. The fact is that this department was not represented in that discussion.

I do not feel it my province to defend dermatology against any attacks on its right to recognition as a legitimate and most important field for special study and special practice. Dermatology is too proud to defend its raison d'être. For more than fifty years the scientific study of skin diseases has been carried on by an indefatigable lot of workers in all civilized countries with results surpassed only by the more conspicuous and brilliant achievements of modern surgery. To charge dermatology with being little more than a mere aggregation of titles of diseases denotes either ignorance, lack of sympathy or wilful vituperation. Nobody realizes more than we dermatologists that the numerous attempts to classify the various cutaneous disorders after the example of other sciences like botany or zoology, have not proved altogether satisfactory; but the respective labors of a Willan and Bateman at the beginning of this century, of the great reformer, Hebra, in the '50s, of Auspitz, Bronson and Jessner more recently, to mention only a few representative names, have not been entirely lost. They have helped to clear up many a dark spot, to group together many apparently different disorders, to separate others of seeming likeness, but distinct in their essential nature. Our nomenclature may seem indeed "horrifying in degree" to the uninitiated, but to the dermatologist the many titles are nothing but excellent servants, intended to promote universal interchange of ideas and never allowed to become our masters. The names are like the short inscription on a painting, useful for ready reference; behind them stands a mass of pathological, histological and etiological study. Let bacteriology get a few years older and you will have a terminology there which will make us poor dermatologists blush for our comparative insignificance. This sneer at our nomenclature reminds me of the kind of diagnoses that are occasionally made in practice, when the patient is told by his doctor "Oh, this is no cancer, it is just skin disease." Are we to go back to that lovely era of humoral pathology, when indeed it was quite an unnecessary ballast to know anything about cutaneous affections, when finer distinctions and differentiations were superfluous, because any eruption on the skin was looked on merely as the outward sign of an impurity of the blood, when the physician without troubling *himself* much whether his patient had the itch, ringworm, acne or eczema, was ever ready with his purgatives, diuretics and alteratives, poured without aim or choice into the poor victim? Horrifying nomenclature indeed! The 62 volumes of the *Archives for Dermatology and Syphilis*, the 30 volumes of Unna's *Monthly Journal for Practical Dermatology*, the dozens of the French *Annales* and our own *American Journal for Cutaneous Diseases*, not to mention the British and Italian periodicals, contain nothing but discussions as to names. The American Dermatological Association, which convenes annually for its scientific deliberations, the triennial International Congress for Dermatology comprising hundreds of the most eminent physicians and surgeons of all countries, the many smaller national and local special societies have little more to do than to wrangle over names! In the idea of our critics at least.

Can I undertake within the limitations of a short address to signalize the scope, the scientific and practical importance of dermatology? This would be impossible. Permit me to give a few illustrations suggestive of what signal service dermatology has been to general medicine.

Let me remind you that the epoch-making studies of Robert Koch on the nature and etiology of tuberculosis have been primarily undertaken on material furnished by that destructive skin affection which is known as lupus. Long before the discovery of the tubercle bacillus in 1880, clinical observation had made it more than probable that there existed a relationship between that local disease and generalized tuberculosis, statistics undertaken by various observers on large material having demonstrated that in more than 70 per cent. of all cases of lupus there existed simultaneously or followed eventually some other manifestation of tuberculosis. Now, when a new era of pathology had been inaugurated, dermatology eagerly took hold of bacteriological methods and proved quite a number of hitherto misunderstood skin affections to be nothing but forms of local tuberculosis. The well-known scrofulous ulcers of early and adolescent life; the wart-like formations often following infection in post-mortem work and known as verruca necrogenica or anatomical tubercle; the so-called tuberculosis verrucosa cutis, an affection occurring in the form of round, raised, papillomatous patches on the hands of butchers, coachmen and others occupied with diseased cattle; the many accidental ulcerations following infection by the tubercle bacillus, as for instance after circumcision, piercing of the ears, washing of infected linen; the rapidly progressive, ominous ulcers on the lips and in the mouth or other mucous outlets, observed in the last stages of consumption, besides some other rarer skin lesions were thus assigned a sure place in pathology. Much of the modern progress in the knowledge of the nature, the therapeutic and hygienic management of this all-important pandemic disease is justly due to the stimulus furnished by dermatological work. And right now we may hopefully look forward to much better success in our fight against that scourge when the magnificent results achieved in Finsen's light-ray institute at Copenhagen for the treatment of lupus, as well as the distinct effects of the Roentgen rays on the same disease make it more than probable that these, as yet somewhat mysterious agents, may before long be utilized against tuberculosis in other parts of the body.

Another example of the value of dermatological study may be furnished by that ever live and interesting chapter, the malignant and benign new growths. It will be readily admitted that nowhere are the conditions for observation and investigation more favorable than on the external integument, which is so frequently the seat of the various forms of epithelioma, sarcoma and other tumors. The transformation of apparently harmless eczema-like lesions into a most serious form of multiple sarcomas of the skin, better known as mycosis fungoids; the formation of numerous carcinomas on the skin of young subjects, who early in life on a dry and harsh skin develop excessive pigmentations in the form of freckles and many small ectatic blood-vessels, a disease first described by Kaposi as xeroderma pigmentosum and usually affecting several members of the same family; the nature of the so-called senile warts and their tendency to metamorphosis into flat epithelioma; the fact that some forms of cancer may remain local in character for many years and indeed have justly been called benign epithelioma, while others exhibit a most destructive energy and tend to rapid multiplication; the relationship of keloid to cancer; the knowledge of multiple melanotic sarcoma of the skin; the investigation within the last few years of those most interesting tumor-like vegetations due to an inoculation of the yeast fungi and termed blastomycosis; the pronounced influence of the systematic use of arsenic in gradually increasing and large doses on certain forms of multiple tumors, particularly those affecting the lymphatic glands known as pseudo lymphosarcoma, or Hodgkin's disease; the decided effect of Fowler's solution used locally only on some forms of epithelioma, a method not to be undervalued in patients to whom the word operation means untold horrors; these are some of the lessons which have been taught by dermatology.

And what of the earnest and unceasing labor bestowed by dermatologists in all parts of the world on the study of that most fearful disease, not of the skin alone but of all organs alike, leprosy? I do not intend to sound an alarm cry here; but believing as I do in the infectious nature of this disease, I regard it of growing import to us. Only two years ago there assembled in Berlin an international congress solely for the discussion of leprosy, its nature and the best means for its mitigation and extermination. As one result of that conference, I may mention the founding of a special journal for leprology, international in character, and supported by collaborators, mostly dermatologists, in all zones. The discovery of an easily recognizable bacillus in all products of lepra by Hansen, has wonderfully helped to instigate a great deal of scientific research and much has been done in the last few years toward the development of more rational methods of treatment, especially by an antileprous serum, though this is still in the experimental stage.

It is hardly necessary to remind you of the enormous importance of syphilis, a disease which no practitioner of medicine, no specialist, whatever his particular field may be, can afford to ignore, for syphilis spares no organ, no tissue. And need I emphasize the value of dermatology in this respect? Almost all the histological and experimental work in this department, all the descriptive detail, the development of the modern scientific methods of treatment, I refer especially to the employment of mercury in the form of hypodermic injections, is due to the work of the dermatologist and syphilographer. Nor have they neglected the many sociological and hygienic problems which are presented by that disease.

The illustrations just cited refer to diseases of a preeminently cutaneous character. But even in fields of purely clinical medicine, dermatology has often contributed to a better and richer pathological understanding. Take for instance diabetes. Very frequently this disease is first recognized by the dermatologist, to whom the patient is directed on account of the prominence of cutaneous disturbances, which are indeed quite manifold: often a more or less severe itching of the skin; again the appearance of numerous furuncles; occasionally even gangrene in some peripheral part, as for instances the toes; as rarer manifestations, large and peculiar ulcerative patches on the lower limbs, first described by Kaposi as dermatitis diabetica; finally, the formation of innumerable smaller and larger yellowish tumors in the skin known as xanthoma diabeticorum.

Medicine in general and neurology especially will always be under obligation to dermatology for work done in reference to the distinctly trophic or neurotic disturbances of the skin. I need only to refer to herpes zoster, popularly known as shingles, that most interesting disease, whose relationship to pathological alterations of the underlying nerves or nearest ganglia has been proved beyond doubt; to symmetrical gangrene of the toes and the finger tips or other peripheral parts, well known as Raynaud's disease; to the various forms of that strange bullous eruption, pemphigus, which we have strong reasons to attribute to deep-seated nervous changes.

Of much general value is the work done by dermatologists in regard to the various drug eruptions. I am glad to mention in this connection two important publications by American authors, J. C. White of Boston, and P. A. Morrow of New York. The untoward effects of our remedies must ever be kept in mind by the practitioner, and among the foremost of these are cutaneous disturbances. Of the long list of drugs with whose action in this respect we are not quite familiar, I will only mention as of chief interest on account of their frequent and varied employment, the iodin and bromid preparations. That potassium iodid very readily leads to a symptom-complex known as iodism, in which is comprised an eruption of small pustules and papules on the forehead, neck and shoulders, is quite well known. But besides these vulgar and comparatively harmless lesions, it is sometimes responsible, even after minute doses, in people exhibiting a special idiosyncrasy, for an eruption of large, copious bullæ which may cover the hands and the whole face and thus become of serious import. Bromids also produce almost inevitably, after being used for some time, the well-known brom-acne, In addition to this, dermatologists have, however, traced a most peculiar, I might say picturesque, dermatosis to its use. The senior students present to-night may still remember the case of an infant which was brought to our clinic last spring. On the hips and limbs and on the face could be seen sharply configurated, roundish and irregular, fungoid elevations of a pinkish color, with a slight central depression of the individual lesions, which proved to be quite firm, large papules. In spite of the apparent resemblance to infantile eczema of the face the diagnosis of a bromid eruption was promptly made and a statement then elicited from the mother that the child had for some time been subject to, and treated for, some sort of nervous attacks, was sufficient corroboration. We soon learned from inspection of the doctor's prescription, that the child had indeed been taking potassium bromid. The mere suspension of this drug was all that was needed for a cure.

Turning from these more or less clinical sides of cutaneous medicine to its purely scientific aspects, I would willingly submit to the judgment of the histologist and bacteriologist, if dermatology has not done more than its share in the advancement of these respective sciences. It might easily fill the space of a separate paper to show in detail what has been accomplished in this respect, and I will only point to that monumental work of Unna on the histopathology of the skin, a classical volume of over a thousand pages and a lasting testimony to the services of that prolific and suggestive writer and worker.

The proposition advanced in the earlier part of this address that the specialist must always remain a physician, that he must be well versed in general medicine, holds particularly good in the practical work of the dermatologist. The man who would look on the skin as a detached organ and treat its diseases from a narrow standpoint is bound to make a failure of his vocation. True, a large number of skin diseases, pre-eminently those of a purely parasitary origin, a very respectable class, by the way, can and should be managed by topical applications only, no matter how firmly the patient may be convinced that his blood is out of order and how eager he may be to get some purifying medicine. Notions of this kind are largely due to the inspiration drawn from the famous advertisements in our dailies and weeklies, the church papers not excluded. To respond to them borders close on quackery. I find patients in this country, as a rule, quite willing and capable of being enlightened, and it is only very rarely that a conscientious practitioner needs to resort to placebos. In this connection I wish to expose that most reprehensible habit of many physicians to feed every skin disorder, irrespective of its meaning, with arsenic in some form. I am fully aware of the beneficial and often curative action of this drug at the proper time and in the proper place, but given indiscriminately, it is more often harmful than useful, and I can not too strongly denounce its light-handed exhibition.

In the majority of skin diseases, on the other hand, which are met with in daily practice, there is indeed an important field for systematic treatment of the underlying cause. The teaching of Hebra, who in his enthusiasm proclaimed the purely local nature of such affections as eczema and acne, have long ago been discarded by modern dermatologists. The young girl who finds her face covered with blackheads and pimples will in vain try all sorts of soaps, salves and lotions. For while in acne there is a local, often parasitary, and besides this almost always a structural, anatomical element in its make-up, we can invariably ascertain important deviations of the assimilative and eliminative functions from the normal standard, and consequent on these we find often changes in the morphological aspect of the blood. Whoever undertakes to treat acne without the most careful attention to the diet, general hygiene and correction of the conditions just alluded to, will be disappointed.

And so it is with eczema. It may sound ungrateful from one to whom the traditions of that old and venerable school of dermatology at Vienna are still as dear as ever, but I can not help declaring and teaching as a result of unbiased observation and study, that I look on eczema as something more than a mere local catarrh of the skin. Sure enough, many instances of that protean disease are primarily due to some local irritation, and in all probability to some sort of parasite of which Unna has lately shown us quite a variety, since he has himself discarded his former Morococcus. These local forms might better be called dermatitis eczematodes. They are, as a rule, easily managed and no physician ought to lose much sleep over them. True eczema, however, the kind that appears often apparently without any external provocation, that recurs in spite of the most careful local treatment and is liable to persist for years, is due to a multiplicity of constitutional disturbances too varied to permit of enumeration here; disturbances which may be conveniently comprised under the designation of autointoxication. As a classical representative of this category, I might mention gout and its congener rheumatism. Nor should we forget that important type of nervous eczema. These kinds of eczema demand for their relief the most circumspective management, require besides a mastery of a good deal of technical detail as regards the topical treatment, a wide acquaintance with general pathology and general medicine. Mark well, it is the combined local and systemic action in such cases which alone can promise success. Mere reliance on dietetic, hygienic or internal treatment can not succeed in removing the deep-seated anatomic alterations of the skin, which are the result of a chronic catarrhal inflammation in loco, leading to hypertrophy in all the layers of the skin. No more would you undertake in the case of a mature cataract, which is due to diabetes, to clear up the cloudy lens by an antidiabetic diet or expect the disappearance of hemorrhoids, the result of an impeded portal circulation, from stimulation of peristalsis alone.

To put before you still further illustrations in order to show the value and importance of dermatology would be, I fear, too severe a tax on your indulgence. Maybe you have already concluded that dermatological nomenclature is horrifying indeed.

There is only one more point which I can not suppress, for it is always near and dear to my dermatological heart, and though I have urged it time and again without response, I shall never tire of repeating that the American schools of medicine, our own not excluded, and the American hospitals, with very few exceptions, make an altogether too insignificant provision for the cultivation of dermatological studies. When, eleven years ago, this college first established a distinct chair for the teaching of skin diseases, and I was invited to hold one clinical demonstration each week, some of my friends used to discourage me by predicting lack of clinical material and consequent lack of interest on the part of the students. It is with pardonable satisfaction that I look back to the record of dermatological instruction in this school during these eleven years. We have succeeded in building up a clinic, which now justifies daily demonstrations in our dispensary and which is ample to illustrate our regular clinical lectures. The students have invariably shown a keen interest in this branch and have, as a rule, left our school well prepared for the demands of ordinary general practice, while a few have even chosen dermatology as a field for special study in which to-day they are conscientious and faithful workers. But I hope for still better work, particularly in the direction of hospital and laboratory facilities. It is invidious to draw comparisons, and almost humiliating to look over to such places as Paris, Vienna and Breslau. The famous Hospital St. Louis in Paris contains hundreds of beds for patients suffering from skin and venereal diseases. Its unique Baretta collection of life-like wax models of cutaneous disorders forms a treasury which perennially attracts a pilgrimage of seekers of instruction. The resources of the general hospital in Vienna, with its almost 300 beds for the same purpose, are too well known to need reiteration here. But even in that comparatively small Silesian town, with its 200,000 inhabitants, in Breslau, you may see a special institute, a large building, exclusively for the advancement of dermatology. It contains several wards, polyclinical rooms, bacteriological and histological laboratories, rooms for photographic, particularly for stereoscopic reproductions, lecture halls, complete bathing arrangements, drug rooms, in short, it is an ideal dermatological household, under the leadership of that enthusiastic master, Neisser, and his assistants. Where is the millionaire who will ever endow anything like it here?

Let us keep our eyes open to our short-comings and possible defects, let us continuously strive for further improvements in our methods of instruction and our technical facilities. Then, indeed, may the day not be far off when our young graduates will cease to wander across the water in search of higher medical education; when, as Osler predicted recently, the current of seekers of knowledge and skill may be reversed toward our own shores. Then the United States of America will be the leaders not only in all spheres of industrial and commercial activities, but also in the higher domain of the science and art of medicine.

ETIOLOGY OF DYSENTERY.*

SIMON FLEXNER, M.D.
Professor of Pathology, University of Pennsylvania.
PHILADELPHIA, PA.

Our imperfect knowledge of the nature of dysentery is not due to lack of opportunity for, or of energy in, its study. The disease, in the past quarter of a century, has not escaped the attention of bacteriologists, although it must be confessed that the results of somewhat extensive studies along these lines have been far less conclusive than might have been predicted. The attempt to establish a common etiological factor for all cases of dysentery has thus far failed. This failure has tended to emphasize the existence of several pathological states for which the term dysentery is employed merely as the collective designation. That these conclusions regarding the disease may, after all, not be in keeping with the facts is at least open to suspicion. When we recall the protean nature of other infectious diseases, there can be no *a priori* objection to the hypothesis that the causative agent of dysentery need not necessarily vary for each of the many types of the disease that have, from time to time, been distinguished.

That the lines of demarcation between the several clinical and pathological types should be inaccurate is not a matter of wonder. Both the beginning and end of any given instance may vary very widely and the symptoms and lesions of cases arising sporadically in temperate climates may agree with those of dysentery occurring endemically in the tropics or epidemically in both localities. The terms "catarrhal," "tropical," "epidemic," and "diphtheritic" are far from signifying sharp-cut entities.

As must always occur when classification of a disease proceeds on clinical and pathological rather than etiological lines, the literature of dysentery is burdened with an interminable mass of appellations indicating the nature of the disorder or the author's conception of its pathological anatomy. Dysenteries, however, are now divided by the chief writers into several groups, depending on the clinical history or the mode of prevalence; thus Osler writes of the acute catarrhal, tropical or amebic, the diphtheritic, and the chronic dysentery. Davidson considers the subject under two headings, 1, according to prevalence—epidemic, endemic, the dysentery of war and famine; 2, on clinical grounds—acute, fibrinous or pseudo-diphtheritic, and chronic dysentery. Kartulis described endemic, epidemic, and sporadic varieties; Manson speaks of a catarrhal and ulcerating dysentery, while Delafield distinguishes in the environs of New York at least five distinct types of the disease, only one of which appears to be due to a specific agent, the ameba coli.

Bacteria have been urged by many investigators as the cause of dysentery. The earlier studies of Klebs, Prior, and Ziegler have now only a minor historical interest, although Ziegler still holds that the relation of certain bacilli to the lesions speaks for their pathogenic action. The early studies of Hlava on the epidemic disease yielded quite inconclusive results. Chantemesse and Widal were somewhat more fortunate in that from five cases of tropical dysentery they obtained a bacillus which, when injected into the stomach or rectum of guinea-pigs, gave rise to diphtheritis, an observation, however, which Grigoriew, who believed that he had isolated the same micro-organism from ten cases of dysentery, failed to confirm. Maggiori obtained from eleven cases of the epidemic disease B. coli communis. This investigator considered it highly probable that the disease was caused by this organism, whose virulence was intensified, a conception also shared by Laveran, Arnaud, Celli, and Fiocca and Escherich, who isolated the same organism from dysenteric cases.

---

* Presented to the Section on Practice of Medicine, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

The studies on this bacillus by Celli and Fiocca are the most important which we possess. Their cases included examples of the sporadic, epidemic, and tropical disease occurring in Italy and Egypt. They paid special attention to the occurrence and action of the ameba coli, so that they are doubly useful. They exclude this organism as a cause of any form of the disease and consider that a variety of the colon bacillus particularly pathogenic, which they designate B. coli dysenteriæ, is responsible for the lesions. A toxin separated from growths of the organism was found to act on the intestines of animals in a manner similar to the bacilli. Results similar to those of Celli were obtained by Del Pino and Alessandri. The colon bacillus is also believed by Escherich to play an important part in the production of colitis contagiosa in children—a disease which in its morbid anatomy agrees with catarrhal dysentery.

The bacilli thus far enumerated, except those of Chantemesse and Widal, show no specific properties. They all represent a well-known bacterial species, constantly present normally in the situations from which they were obtained in disease, and whose only unusual properties were increased virulence when tested on animals, and a capacity to set up enteritis when injected into the intestines of dogs and cats.

Investigation of an epidemic of dysentery which prevailed in Japan yielded different and apparently more convincing results. Ogata isolated fine bacilli, which liquefy gelatin, stain by Gram's method, and set up in guinea-pigs and cats intestinal ulcerations. A similar organism was later obtained in Padua by Vivaldi, since which time it appears not to have been found again. This list covers the bacillary species isolated in cases of dysentery, with the exception of an organism obtained by Shiga, who also studied the disease prevailing in Japan. This investigator's studies, which have a very direct value on my own, are deferred for the present.

On the other hand, a causative rôle in the production of dysentery has also been ascribed to the pyogenic cocci. Besides being found in association with bacilli by several of the investigators already mentioned, they have been regarded as the chief pathogenic agents by Zancarol, whose studies were carried out in Alexandria, and very recently by Ascher, who investigated cases arising in Eastern and Western Prussia. Similar observations were made by Silvestri, of Turin, and by Bertrand and Baucher in France. These cocci, especially the streptococci, were capable in certain instances of setting up, in cats, dysentery and liver abscess. An especial variety of endemic dysentery occurring in Cochin China, yielded Calmette the B. pyocyaneus. The same micro-organism was isolated from a small epidemic of the disease occurring in New York state by Lartigau; in another epidemic in children prevailing in Canada by Adami, and in certain sporadic cases, by Barker in Baltimore.

Protozoa have also been brought forward as the cause of dysentery. These organisms differ from the bacteria in not existing in easily demonstrable forms or numbers in the dejecta in health and the number of species occurring under all conditions is small. Among the protozoa the amebæ have achieved the distinction of being connected in a causal relation with endemic dysentery. Since the studies of Kartulis, Councilman and Lafleur, and Kruse and Pasquale, so firmly has the idea of this connection taken hold of the popular medical mind that the designation "amebic" as synonymous with "endemic" or "tropical" dysentery has been widely adopted; and yet the evidence on which this belief is placed can not be regarded as convincing. Until we shall have gained other means of differentiating amebæ than we now possess, and moreover until we are able to control their development with at least as great perfection as in the case of bacteria, the question of the precise part played by them in dysentery can not be satisfactorily determined.

The last ten years have seen a modification of the views regarding amebæ as causes of pathological conditions in human beings. That these organisms exist in diseases other than dysentery was conclusively proved by the early observations—Cunningham, Lewis—on choleraic discharges. Grassi found them in diseases so varied as typhoid fever, cholera, pellagra and colitis secondary to tumors. He also found them in the dejecta of healthy individuals, a fact further established by Calandrucci, Massiutin, Kruse and Pasquale, Gasser and Schuberg. It can, therefore, no longer be held that amebæ are necessarily pathogenic when found sojourning in the intestine of man.

That these organisms, when combined with bacteria, may cause intestinal lesions and even ulceration, is now established. The experiments of Kartulis and Kruse and Pasquale with the contents of hepatic abscesses supposed to be free from bacteria are all but convincing in so far as they are supposed to prove the capacity of amebæ alone to set up such changes. Councilman and Lefleur believed that the amebæ alone produced the intestinal lesions. Kartulis, on the other hand, sees in the occasional diphtheritis evidence of the action of bacteria, while Kruse and Pasquale have followed the latter in their penetration into the coats of the gut where they lie side by side with the amebæ, or even precede them in the invasion.

We may, I think, sum up the present knowledge of the cause of dysentery in the following way:

1. No bacterial species yet described as the cause of dysentery has an especial claim to be regarded as the chief micro-organism concerned with the disease.

2. It is unlikely that any bacterial species that is constantly and normally present in the intestine or in the environs of man, except where the disease prevails in an endemic form, can be regarded as a probable cause of epidemic dysentery.

3. The relations of sporadic to epidemic dysentery are so remote that it is improbable that the two diseases are produced by the same organic cause.

4. The pathogenic action of the ameba coli in many cases of tropical and in certain examples of sporadic dysentery has not been disproved by the discovery of amebæ in the normal intestine, and in diseases other than dysentery. While amebæ are commonly present and are concerned in the production of the lesions of

subacute and chronic dysentery, they have not thus far been shown to be equally connected with the acute dysenteries, even in the tropics. In the former varieties, bacterial association probably has much influence on the pathogenic powers of the amebæ.

The Dysentery of Japan and the Philippine Islands.—Every year, especially in the summer and autumn, dysentery prevails in Japan. The epidemic studied by Ogata occurred in the province of Oita. Lesions in the intestine are described in one instance, death having occurred on the eleventh day of the disease. The lower segment of the small intestine was hyperemic. The large intestine was greatly swollen so that the lumen was almost obliterated. The mucous membrane was hyperemic, and presented a deep bluish-red color, while the mucous membrane of the transverse and descending colon showed small ulcers, which were so numerous as to give to the membrane a sieve-like appearance. The peculiar bacilli described by him were obtained from these cases.

The most recent bacteriological study of Japanese dysentery has been made by Shiga. Out of the considerable number of cases of the disease occurring in Tokyo in 1897, thirty-six were subjected to examination. Shiga recognized that in order to prove that an organism which is suspected of standing in etiological relation to a disease is really the causative agent, four points have to be demonstrated, 1, that organism must occur constantly; 2, it must be a species not present normally in the diseased parts; 3, it must be pathogenic, and produce in experimental animals lesions similar to those from which it was obtained; and 4, it should, in virtue of its pathogenic activity in man, show the Widal agglutination reaction with the blood-sera of those who have suffered from the disease. From the series of cases examined, there was obtained from the dejecta and intestinal contents and walls, and from the mesenteric glands a bacillus which fulfilled all these requirements, and which was regarded as the cause of at least Japanese dysentery.

Before describing this organism, I wish to direct your attention to the dysentery prevailing in the Philippine Islands, especially in and around Manila. The report of the surgeon-general of the army for 1899 contains a tabulation of diseases observed among the American troops during the first four months of the American occupation of Manila. In it the dysenteries are included with the diarrheal diseases. The total number of cases reported was 445, death-rate being 0.48 per cent. The comment made is that the malarial diseases exceed their prevalence in the United States in the proportion of 370 to 96, and the diarrheal diseases in the proportion of 445 to 116, or about four to one in both instances. This compilation fails to give an adequate idea of the extent, severity and mortality of dysentery in Manila. Although the figures were not obtainable, I was convinced from nearly three months' residence in Manila that the enteric diseases, of which dysentery was the most frequent and important, were the chief causes of disability and mortality among the land forces of the American army.

The disease occurs in two main forms: acute and chronic. The stools and intestinal contents were scrutinized for amebæ. These organisms were absent or very difficult to find in the acute cases. In the chronic forms of the disease, in which ulcers were present, they were variable as to actual occurrence and number. Large hepatic abscesses, usually single, were encountered in a number of these cases.

The morbid anatomy of the chronic disease agrees in part only with that of the so-called amebic dysentery. The pathological changes in the acute disease differ widely from those of the chronic cases. I shall give an illustrative example: American soldier, dead on the sixth day of the disease. The entire large intestine from the cecum to the rectum is dilated and the walls of the gut are thickened. The mucous membrane is swollen, its consistence much increased, and the normal folds are thrown into elevated coarse corrugations. The general color of the mucous membrane is deep red, but there are present many brighter spots, evidently due to hemorrhage. A false membrane, consisting of scattered white elevations, occurs on the surface. Distinct ulceration can not be made out with the naked eye.

Bacteriology of Philippine Dysentery.—In the study of the bacterial flora of the disease, acute and chronic cases were utilized. Plate cultures in agar-agar were employed. The material for the cultures was obtained from the dejecta and from the intestinal contents after death. From the separated colonies slant cultures were made. Those consisting of the pyogenic cocci, which were never absent, were not studied further. Portions taken from the several bacillary colonies were tested on various culture-media with the result that two distinct types of organisms could be distinguished, especially in the acute cases. Their properties are as follows:

TYPE 1. Bacillus of average size; variable in length, usually occurs singly, sometimes in pairs, but only very rarely in filaments. The ends are slightly rounded. Moderate motility. Gram's stain is negative. Morphology: colon—typhoid type.

Growth took place on all culture-media at the room temperature, but better in the thermostat. Gelatin was not liquefied.

The colony forms resemble those of B. typhosus; after many successive transplantations on artificial culture-media, the colonies and slant growths become more opaque and abundant.

Potato: Growth takes place along the line of inoculation and spreads beyond. After some days it is a little elevated and of a pale-brown tint. On unfavorable potatoes the growth is slight, moist and membraneous, resembling that of B. typhosus when typical, excepting for the greater amount of moisture.

Sugar-agar is not fermented gaseously; in glucose media a moderate acid production takes place.

Litmus-milk: At first a very faint lilac color appears. It is discernible after 24 hours, but more marked at the end of 48 or 72 hours. After a lapse of 6 to 8 days alkali begins to be produced, which increases in amount until the litmus is rendered deep-blue in color. No coagulation of the milk ensues.

Indol: This body is variable in its formation. Even in sugar-free bouillon if may fail to appear, or be produced in small quantities only.

Suitable cultures of this organism, when tested for the agglutination reaction with the blood-serum of persons suffering from dysentery, whether the host or another individual, give in many cases a positive reaction.

TYPE 2. Present in all instances. In the acute cases it may not predominate, being less numerous than the members of Type 1. In all others it is the predominating bacterium. Its properties are variable, but agree with those of the group of B. coli communis. The main variations relate to the extent and rapidity of growth on the several culture-media as exhibited by the color, thickness, etc., of the colonies. The sugars are broken up with the formation of gas. Litmus-milk is reddened promptly, but coagulation sets in at variable intervals—sometimes after twenty-four hours, at other times not for several days or weeks. Indol is produced, but can not be demonstrated in all cases within twenty-four hours. In morphology the bacillus resembles B. coli communis. Some specimens are motile at the end of twenty-four hours; in others, motility could not be demonstrated.

The results of the agglutination tests varied according as the blood of the host or another individual was employed. With the host there was frequently a reaction in low dilutions; with another person the reaction was rarely and very inconstantly obtained.

Before proceeding to the assumption that this organism was concerned with the production of the intestinal lesions of dysentery occurring in Manila, its absence from the stools of healthy persons and those suffering from other diseases must be established. Strong presumptive evidence of its being an unusual inhabitant of the intestine of man may be gathered from the facts already known concerning the ordinary intestinal flora. But as such observations would not suffice for a new region and under new conditions, the organism was searched for in other persons who had been in close association with those suffering from dysentery and also in inhabitants of other parts of the Island of Luzon. The organism was not demonstrated in healthy dejecta or in the evacuations of persons (native Filipinos) suffering from beri-beri. A further argument in favor of its restricted distribution is furnished by its absence from cases of chronic dysentery or its marked reduction in numbers.

Pathogenicity.—The pathogenicity of the bacillus type was studied, soon after its isolation, on mice and monkeys in Manila, and on various animals in this country with cultures brought back from the Philippines.

Mice are susceptible to subcutaneous injections, but react more readily to intraperitoneal inoculations. According to the dose, death takes place in from 12 to 48 hours—more rarely after several days. The site of the puncture shows edema, and when the inoculation is made into the peritoneum a slight turbid exudate is present. Bacilli are present in very large numbers in both situations and there is a general invasion.

Guinea-pigs react much in the same way as mice. The dose required is slightly larger, but successive inoculations quickly increase the pathogenicity. At first the organisms remain confined to the site of injection, but when the virulence has become intensified the body is invaded. Intraperitoneal injections cause a sero-purulent peritonitis, many bacilli being contained within polymorphonuclear cells. The intestines are hyperemic; the contents are watery and the bacilli can be cultivated from the fluid portions.

Subcutaneous injection into rabbits gives rise to a localized swelling, which is sometimes followed by death. At other times an abscess forms and perforates the skin, after which recovery may take place.

Cats and dogs are also susceptible to feeding with cultures, the first after the administration of croton-oil, the second directly. In both enteritis is set up; an increased secretion of mucus takes place, hemorrhages may occur, and bacilli are cultivatable from the dejections and intestinal contents. Ulceration does not take place.

Tests made with dead cultures on guinea-pigs show them to be highly toxic.

If the bacillus described is of significance in the etiology of dysentery, it must occur with regularity in the disease. Whether or not it will be found to have the distribution that is necessary in order to establish this relationship can only be determined when the study is carried on in widely different places and in all forms of the disease. That the bacillus is identical with the organisms obtained by Shiga in the epidemic of dysentery which prevails in Japan, there can be no reasonable doubt.

I have recently been enabled to study bacteriologically and pathologically a case of chronic Puerto Rican dysentery contracted during the Spanish war. The autopsy showed the colon to be greatly thickened, especially along the sigmoid flexure. The mucous membrane presented a roughened surface without showing pronounced ulceration. The submucosa was thickened also, and there was considerable contraction. A very small amount of pseudo-membrane was present over the lower part of the sigmoid flexure. Bacteriological examination yielded two types of bacilli, the prevailing one agreeing with the type of B. coli communis, the other with bacillus type 1, already described.

The bacteriological studies of Egyptian dysentery published by Kruse and Pasquale contain numerous references to typhoid-life bacteria. Critical examination shows the majority to belong to the group B. coli communis. Still other examples of bacillus similar to, and possibly identical with, the B. dysenteriæ have been found in dysentery, although they are not suspected of standing in any etiological relation to it. Pansini studied four cases of abscess of the liver, three of which had followed dysentery. The bacilli which were isolated resembled B. typhosus; indeed, Pansini could not distinguish between the two series. Babes also, although only in a single instance, isolated such an organism from a case of dysentery.

The question naturally arises: In what way does the bacillus Type 1 differ from B. typhosus? When the properties of Shiga's bacillus and that of the Eberth-Gaffkey organism are compared, the criteria of difference are not numerous. The main features, however, are as follows: The former shows less marked motility when first isolated and a tendency rapidly to lose motility in artificial cultivations; it displays a more uniform generation of indol; after a brief preliminary acid-production in milk, there follows a gradually increasing alkalinization; it is inactive to blood-serum from typhoid cases, but reacts with serum from dysenteric cases to which the B. typhosus does not respond.

The Agglutination Test.—The tests in the case of the bacillus isolated in Manila were made at the time with blood obtained from acute and chronic cases of dysentery, and after the return to this country, with the blood-serum from the case of the chronic Puerto Rican disease as well as with blood obtained through the courtesy of Assistant-Surgeon Craig, stationed at the Presidio at San Francisco, the last having been obtained from convalescents and other soldiers suffering from chronic dysentery who had returned from the Philippines. The results were positive in the cases of the acute disease in which infection with the bacilli was established. It was also positive with the blood of the Puerto Rican case of chronic dysentery, but was inconstant with blood from other chronic cases. Dr. Osler has told me of his experience. In several cases of amebic dysentery that have come to his attention in the Johns Hopkins Hospital, the blood-serum has not caused agglutination of the dysenteric bacilli obtained in Manila. In a case of the

Puerto Rican disease a positive reaction was obtained.

These results are, I think, suggestive of the nature of tropical dysentery. The typical acute and infectious variety is probably bacillary in origin, and the indications are that the particular bacillus which has been described is the cause of this variety of the disease. On the other hand, the chronic form of the disease would appear to be dependent on at least two sets of causes: the one representing a continuation of the acute disease and probably due to the same micro-organism, the other being due to a different organism and apparently the ameba coli. The first variety of the chronic disease only may be expected to give the serum reaction with the B. dysenteriæ.

Protective Inoculation and Serum Therapy.—It is not unreasonable to hope that with the discovery of the specific cause of dysentery, particularly if it be a bacterium capable of being artificially cultivated, means will be found by which protective inoculation may be carried out with effect and safety. The fundamental conditions underlying such immunizations are now fairly established, and two general methods of accomplishing such results are open to investigation. In the first place, an active immunity may be achieved through the use of cultures of a determined grade of activity; in the second, the serum of animals may be employed either as a therapeutic agent or to provide a passive immunity.

It has been found possible, through the use of cultures destroyed by heat or the addition of chemicals, to protect small animals from the effects of subsequent inoculations of the virulent bacilli. Larger animals, such as the goat, when treated first with the dead and afterward with the living cultures, develop a gradually increasing resistance to the inoculations; their blood-serum assumes highly agglutinating qualities for the bacillus, and coincidentally acquires protective and healing properties. My own experiments relating to this topic have been carried out on small animals only, as no patient with acute dysentery has been seen by me since the serum from the goats has been available. Shiga has, however, been able to test the serum on human cases.

According to Dr. Eldridge, up to Nov. 1, 1899, Shiga treated with serum cases as follows: 1898, in Laboratory Hospital, 65 cases, death-rate, 9 per cent.; 1899, in Laboratory Hospital, 91 cases, death-rate, 8 per cent.; 1899, in Hirowo Hospital, 110 cases, death-rate, 12 per cent. During the same period of 1899 there were under ordinary treatment at Tokyo: at Honjo Hospital, 166 cases, death-rate, 37.9 per cent.; at Hirowo Hospital, 53 cases, death-rate, 37.7 per cent.; at Komogome Hospital, 398 cases, death-rate 34.6 per cent; in private houses, 1119 cases, death-rate, 28.5 per cent.

I should, however, expect greater benefit from a species of vaccination, especially in those exposed to the endemic or the endemo-epidemic dysentery of the tropics. The encouraging results of the injections of the dead bacilli of Asiatic cholera makes the use of a similar procedure in persons exposed to dysentery advisable. The practical details of such inoculations will, of course, be established only after trials, preferably on human beings who are anxious to submit to this method of treatment.

Very little remains for me to say at the present time. It is only natural to ask whether the results given in the last half of the paper justify a belief in a specific organism of dysentery. My own sense is against that belief, although it must be conceded that the varieties of the disease are fewer than the clinical and pathologico-anatomical conceptions of this time would lead one to suppose. I am disposed at this time to view tropical dysentery as consisting of a bacillary and amebic form separable in their early and later stages by their clinical histories, their etiology and pathological anatomy. Whether epidemic dysentery may have a simpler etiology future studies will be necessary to decide. The view expressed by Shiga, to the effect that the bacillus isolated by him is the cause of the epidemic disease occurring in Japan, may be followed by the establishment of the same organism as the cause of other epidemics. My own observations prove the wide distribution and pathologic activities of the organism as well as its relations with a certain class of dysenteries.

NOTES ON TROPICAL DYSENTERY.*

JOHN HERR MUSSER, M. D.
PHILADELPHIA.

Professor Flexner has made such exhaustive remarks on the subject that it remains for me only to present the clinical history of a case. I trust I may be permitted to state also the impressions I received from consideration of the combined clinical and pathological features of the case. The impressions were new to me, partly because of ignorance and partly because it was the first opportunity I had of observing the clinical course and the pathological findings. I had seen tropical dysentery, and associated it with the group of symptoms we are accustomed to see in our climate; or with the more severe types seen during our civil war, with which we were made familiar by the writings of Woodward and others; or with the amebic form, for our more precise knowledge of which we are indebted as much to our colleagues, Councilman, Lafleur, Osler and Flexner, as to any other writers.

Toxic Symptoms.—In the case to be reported we find inflammation of the intestinal tract with its train of symptoms, we find an afebrile course, extreme emaciation and a profound toxic state terminating in the familiar typhoid condition. With these symptoms, the strikingly sallow, pallid hue of the skin, which I had seen in other cases, and which was attached by me to the ailment, was observed.

Serum Diagnosis.—In addition to the interesting toxic phenomena, the serum agglutination, as performed by Dr. Flexner with cultures of the bacillus of Shiga—the bacillus dysenteriæ—proving that the tropical dysentery of Porto Rico was similar to that of the Philippines added thrill to the interest of the case. Moreover, here again was applied a method of diagnosis, which with increasing experience seems to grow in value.

Scorbutic Symptoms.—During the period of observation, symptoms of scurvy set in so that, had we not had the positive results of the serum agglutination we might have thought the case was one of aggravated scurvy. So similar were the symptoms, we felt justified in resorting to antiscorbutic measures. It is needless to say they availed nothing. Nevertheless, the sore and bleeding gums, the subcutaneous hemorrhages, the complexion, the boils and the bloody flux tallied with many of the descriptions of old-time scorbutus.

The Anatomical Findings.—It could not be otherwise than noticed, that in spite of the grave and extensive symptoms, but relatively few anatomical changes were found. The small amount of ulceration of the intestinal tract contrasted strongly with the large ulcers and sloughs in amebic dysentery. Then, too, there were none of the embolic phenomena seen in the latter infection. The extent of the anatomical lesions were, on the whole, disappointing. Briefly told, the story of the case is as follows:

---

* Presented to the Section on Practice of Medicine, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

G. R., aged 32, white; soldier; native of Kansas; admitted Oct. 12, 1899.

Family history: Father and one brother living and well; mother dead, cause unknown; one brother died of measles.

Previous Personal History: Has never been ill excepting with whooping-cough. At the age of 21 he joined the army, and has been a soldier until two months ago. During the Spanish-American war, he was camped near Mobile and Tampa, but did not suffer from any disease while there. He was in Porto Rico 11 months, and while there contracted conditions from which he is now suffering. He has had gonorrhea several times, but is not troubled with it now.

History of Present Illness: Disease began, after being in Porto Rico about three weeks. Many others began to suffer at the same time. Water and food while sufficient in amount, were bad in quality. Diarrhea was his chief symptom, and he had as many as 10 and 12 stools daily, and sometimes half his night would be spent on the water-closet. Associated with this was much rectal tenesmus. His stools contained much mucus, were watery to a degree, and some blood was found in them. At one time he passed something looking like a piece of bowel covered with mucus. During, and before having a stool he often had crampy pain; relief would come after having had a number of stools. He did not pass much urine after these attacks began. There was a constant bearing down pain over base of bladder, which is not relieved by anything. Nausea and vomiting often accompanied diarrhea, and vomit was of about the same character as stool—watery mucous and blood. Many symptoms of indigestion were present during these attacks; eructations, flatus and distention of abdomen, bad taste in mouth, coated tongue, and lack of appetite. Sleeplessness, burning pain along vertebral column were present continuously. He claims to have weighed over 200 lbs., before going to Porto Rico; weight on admission 120¼ pounds. Within three months he has noticed pains in his shoulders, and has had numerous boils on different parts of body, within the year.

Condition on Admission: Patient complains of four different things: a diarrhea, pain over bladder, pains in both shoulders, and boils. He is a tall man—5 feet 11¾ inches—with a large frame, this frame being covered sparely; weight 120¼. Skin of face is sallow, old parchment-like in appearance, but mucous membranes are pale. Pupils equal; react to light and accommodation. Arteries not tortuous. Epidermal scaling over thorax. Chest very prominent; badly emaciated; expansion good and equal; tactile fremitus normal. Percussion resonance normal. Respiratory resonance and fremitus normal. No râles anteriorly or posteriorly. Heart normal, except slight accentuation of second sound. Abdominal examination negative. Numerous scars in different parts of body due to boils. Over prominence of buttocks on right side, and tuber ischii on left side, two circumscribed areas of inflammation; furuncles at their height.

October 13: Urine, normal; sp. gr. 1016, acid; turbid; amber; no albumin; no sugar. Stools: no ameba; milk globules; no blood; mucus in quantities; contains curds; undigested masses of different colors; offensive odor. Blood normal.

Treatment: Patient is put on milk diet, f℥vi every two hours; urine, and bowel movements are noted in number and character.

October 14: Patient has had 9 movements within 48 hours; character as described. A large furuncle over right buttock was opened and curetted; a teaspoonful of purulent material escaped. T. P. and R. are normal, and patient feels much more comfortable.

October 18: While patient says that he feels much improved, there is no sign of abatement in his dysenteric condition, number of stools averaging 3 in 24 hours; character of stools has changed but little, if any.

October 19.—A new furuncle is showing itself at shoulder.

October 23: Stools have diminished to 2 in 24 hours, and patient feels quite well. He had some nausea with vomiting yesterday, but has recovered to-day. Color of stool is brown, characteristics otherwise unchanged. He has been put on meat diet. Enemata of silver nitrate 1 to 20,000 are ordered.

October 27: Treatment as above; condition unchanged.

October 31: Patient passed a partially formed stool; enemata are 1 to 16,000 strong.

November 14: Patient has but one or two bowel movements daily; occasionally they are partially formed, but there is comparatively little improvement as regarding consistency. His appetite is poor, and he tires of all food very readily. He is losing in weight right along, and seems to be getting weaker. His sleep is not especially sound. Heart seems normal; both sounds are strong. He has a number of purpuric spots, varying in size from a pinhead to a split pea, which he states he has had continuously during the past four months; first condition usually of larger spots; furuncle, which after evacuation of pus, resulted in the persistence of purpuric spot. Since his admission, he has had two large boils on right shoulder; these were surrounded by various sized areas of hemorrhagic effusion. Cultures from pus revealed staphylococcus albus. About three days ago, he began to complain of soreness of gums. They are quite reddish and edematous, but have never bled.

November 26: Patient seems not to assimilate food too well; his weight diminishes at each weighing. Last Monday (Nov. 21) he weighed but 100 pounds. The number of stools is also again increasing. Fecal material, examined two days ago for tubercle bacilli, but did not reveal any.

December: Patient is rapidly failing in every respect. There is little left of him besides skin and bones; condition of bowel movements has not changed; they are liquid and semi-liquid, brownish-green in color, containing undigested material, curds, mucus, and the last few days also some blood; odor is sour; no fecal odor. Appetite has been failing for some time. Chest examination is entirely negative. He occasionally has some pain in abdomen. Temperature has been as low as 95.6, and is continually subnormal; body cold and clammy. Stools have been examined microscopically, and contain mucus strands, fat globules, some blood and numerous bacteria. Urine is normal in every respect.

December 15, 1899: Emaciation continues; skin has for some time been dry and brittle, numerous scales all over; hair-pits all over body are covered by brownish scales; tongue is dry and glassy, side covered by white coating; teeth have sordes; voice is thick and low; complains of dryness of entire laryngopharyngeal tract. Examination of lungs shows no change; heart-sounds weak, but nothing abnormal. Abdomen boat-shaped; has had considerable pain in epigastrium for several days past; better to-day. No new hemorrhages over limbs. Joint surfaces look red; skin ready to break. Appetite good, craves, and eats ravenously of oysters, milk, etc. Temperature varies between 95 and 97. Pulse is fairly strong at about 90. Respirations vary between 12 and 15. During sleep sink as low as six. Patient feels much warmer than a week ago. Bowels move almost continually now; to-day a brownish liquid, with fecal odor.

AUTOPSY, DEC. 18, 1899, 10 A.M. UNIVERSITY HOSPITAL.
PERFORMED BY DRS. SAILER AND FLEXNER.

External Appearance: Body of man, extremely emaciated. Marked post-mortem discoloration on abdomen. Small sore covered by scab on right shoulder; another on the left lumbar region, brown; injected spot on right hip; numerous scars and ulcers on right leg: thickened fissuration over right knee. No rigor mortis.

Peritoneal Cavity: Small amount of reddish fluid. The wall of the colon contains areas of dark-black pigmentation. There is a slight injection of the peritoneal surface, particularly about the hepatic flexure. The glands of the mesocolon are all enlarged to the size of peas, and of moderate consistency. The mesenteric glands are also enlarged, pale-gray, apparently covered by dilated lymph-vessels. The lymphatic vessels in the peritoneum are all greatly distended. The caput coli and small intestines are moderately distended. The lower border of the stomach is below the ribs; position nearly horizontal. The lower border of the liver is below the costal border. The left pleural cavity is clear. The right pleural cavity contains a few cubic centimeters of clear, straw-colored fluid. The right side of the pericardial cavity contains a large diverticulum, which extends from the peritoneum into the right pleural cavity; it communicates with the pericardial cavity by an opening .5 cm. in diameter.

Heart: Very small. Epicardium slightly thick and opaque. It forms ridges accompanying the blood-vessels. The latter are tortuous and the veins are slightly distended. There is a small patch of dense, white thickening on the anterior surface of the right ventricle. The right auricle is contracted. Foramen ovale is not patulous. No valve over the coronary vein. The tricuspid orifice admits two fingers; endocardium is clear and transparent. The right ventricle shows slight thinning of the walls, the muscle being 4 mm. in thickness. The muscle is brown and soft. The pulmonary valves are normal. The pulmonary artery is small, 6 cm. in circumference. The left auricle is small; endocardium is pale and opaque. The mitral valve admits one and a half fingers; mitral leaflets normal. The wall of the left ventricle is thin, measures 9 mm.; brown in color, contains trabeculæ of connective tissue. There is a slight atheromatous change in the anterior leaflets of the mitral valve. There is slight sclerosis at the base of the aortic valve and thickening of the corpora arantii. Willow-tree marking at the base of the aorta. Coronary artery is normal. Weight of heart, 160 grams.

Left Lung: Moderate anthracosis of apex and edges of lung. Lungs are pale and show considerable bullous emphysema, particularly at the apical edges. The bronchial glands are anthracotic and slightly enlarged. Surface of section is pale pink.

Right Lung: Apex anthracotic; incomplete separation of the two upper lobes.

Left Adrenal: Normal. Fatty degeneration in cortex. Small accessory below lower end.

Right Kidney: Normal vessels. Ureter not distended. Substance of the kidney is firm. Similar to the left. Weight, 117 grams.

Right Lung: The posterior surface of the upper lobe shows hypostatic pneumonia. On the anterior surface of the lower lobe there is an area of consolidation, sharply limited, of irregular shape, reddish color. The pulmonary tissue resembles that of the left lung.

Spleen: Small. Capsule thickened, wrinkled. Consistence firm. Trabeculæ markedly hyperplastic.

Renal Vessels: Normal. Ureter not dilated. Left kidney very firm, capsule strips readily, although slightly adherent. The cortex is finely granular. Stellate veins injected. On section the cortex is slightly thick. The glomeruli are greatly distended. The pyramids are normal. Weight, 117 grams.

Mesentery: Deeply discolored, the result of post-mortem decomposition apparently.

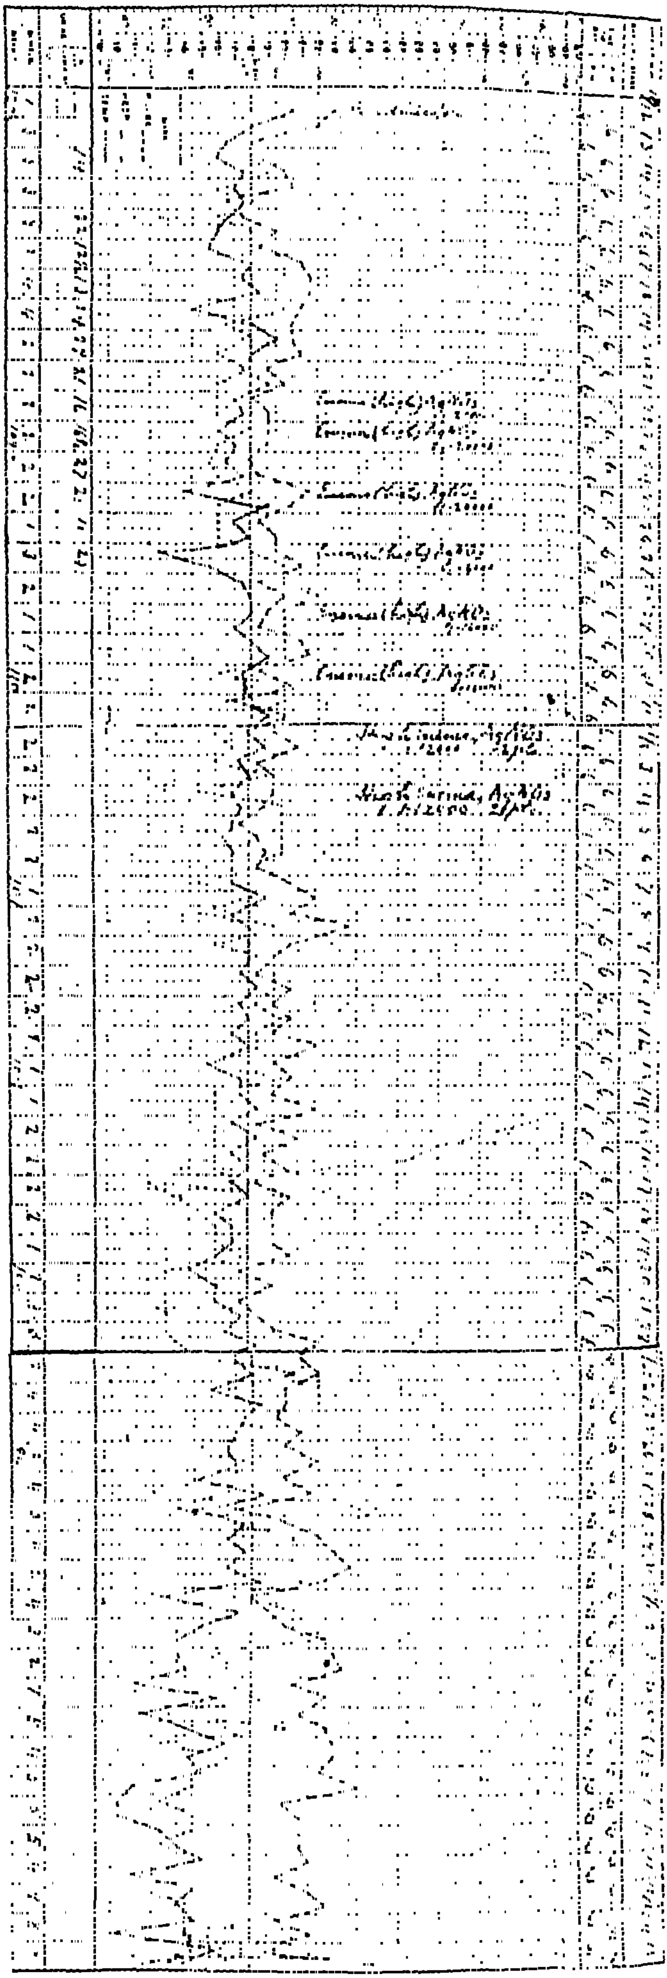
Mucous membrane of the stomach is smooth, soft and covered with mucus containing bloody pigment. Cardiac orifice dilated. The wall of the esophagus is thickened. The mucous membrane contains hemorrhagic pigment. The mucous membrane of the duodenum shows fine brownish pigment. The bile-duct is freely patulous.

Pancreas: Soft. Tissues apparently normal.

The intima of the aorta is pale, smooth. The aorta is elastic.

The lymphatic follicles in the duodenum are considerably distended. Throughout the whole intestinal tract there is fine granulation, more marked in some places than in others. No ulceration; slight hypostatic congestion of certain areas.

Liver: Firm; capsule transparent. Weight 1160 grams. Section normal.



Large Intestine: The peritoneal surface, particularly along the sigmoid flexure, shows dark points and lines of discoloration. There are no peritoneal adhesions. On opening the intestine the rectum and sigmoid are contracted, whereas the transverse colon is distinctly dilated. The intestinal mucosa is thickened throughout, and there are recent hemorrhages into its substance. Throughout the entire length there are present, in addition, numerous, dark, slaty areas of pigmentation, indicative of old hemorrhages. No definite pronounced ulceration is present. The general mucosa presents a granular appearance, and there are superficial areas of denudation of the epithelium. On section the submucosa is firm, but not greatly thickened, excepting in the lower part of the intestine, where there is much contraction. In the region of the transverse colon the mucous membrane is also edematous; that of the cecum is less involved and the small intestine has entirely escaped; only in the lower portion of the sigmoid flexure is there an irregular and small development of pseudo-membrane.

Anatomical Diagnosis: Dysentery. Ulcerative and pseudomembranous colitis. Infarction of lung (?). *Anemia universalis.*

BACTERIOLOGICAL PROTOCOL.

Cultures from liver, spleen, bile, infarction of lung, mesenteric gland, sterile after twenty-four hours in the thermostat.

Petri-plates were made from the intestinal contents taken from the hepatic and sigmoid flexures by burning the surface of the intestine before their removal. Plates were also made from the contents of the large intestine after removal at the autopsy and opening. All plates which were crowded with colonies were discarded; only discrete colonies were selected, from which various kinds were transferred to glucose-agar. From the many transplantations made, a small number only showed at the end of twenty-four hours *no gas formation.* These on comparison showed similar growths.

Coverslips gave short bacilli with rounded ends, showing moderate motility. Transplanted to the milk there is produced at the end of the first twenty-four hours a moderate acid production which, after a lapse of several days, is succeeded by an alkaline reaction of the milk. No coagulation. Gas is not made in any of the sugar media.

The organism corresponds with the bacillus dysenteriæ isolated from cases of dysentery occurring in Manila.

In addition to the case recorded I had the opportunity, through the kindness of Dr. Wilson, of Beaver, Pa., of seeing a case with him. It corresponded in clinical features with the one just recorded, save that scorbutic symptoms were absent. The disease was contracted in the Philippines, eleven months previously, but despite change of climate and the excellent care and treatment of Dr. Wilson, who early recognized the gravity of the case, the course of the disease was not abated. The gravity of the infection and the intensity of the intoxication can be realized when we consider that a lusty youth of two and twenty could be reduced from over 200 pounds to less than 90, and the flower of his country, be carried to his grave. Our new possessions bring to the medical profession new responsibilities in combating these dire diseases.

DISCUSSION ON PAPERS OF DRS. FLEXNER AND MUSSER.

Dr. William Osler, Baltimore—I have had some experience with this subject during the past six months. When the Doctor returned from Manila and told me about the bacilli I think the impression was at that time that the ameba would have to take a back seat in cases of dysentery. We had one instance admitted to the ward; he was a soldier from Porto Rico with dysentery which had lasted some months. No bacilli could be discovered. An interesting point was regarding the blood brought from Manila where the bacilli were obtained. Also, Dr. Flexner's second point, in amebic dysentery whether the bacilli could be outlined and whether the blood agglutinated would react with Shiga's bacillus. We have had six cases of the ordinary type of so-called amebic dysentery, but the blood did not react with Shiga's bacillus, which would indicate distinctly that the disease is separate and distinct from the dysentery as met with in the tropics. I should like to ask Dr. Flexner if this dysentery, which is growing so wide-spread, is not probably the same form which occurs in this country in poor-houses and jails, and which occasionally is seen in the hospitals and which has been locally epidemic. These features are quite different from the ordinary amebic dysentery.

Dr. Norman Bridge, Los Angeles—I should like to ask Dr. Flexner if typhoid fever may occur in conjunction with the form of dysentery which he has described, and if the blood-serum of the dysenteric patient will produce the Widal reaction of typhoid; that is, if it will agglutinate a typhoid culture? I ask these questions because of my observation of a patient in hospital, a year ago last fall, whose history was substantially like that of the patient referred to by Dr. Musser, who had all the appearances he describes—great prostration, purpuric spots, etc. The patient had been a soldier in Cuba, and I supposed the case to be one of tropical dysentery until the Widal reaction of typhoid fever was produced. The patient died a few days after purpuric spots appeared. In another case under observation in hospital within the past three or four months, the same symptoms were present, purpuric spots and all. The patient was a soldier who had returned from Manila, and he died with the dysentery symptoms. In this case no Widal reaction could be produced.

Dr. C. H. Hunter, Minneapolis—It may not come amiss to report two cases of dysentery that came under my observation. In one, a soldier belonging to the 13th Minnesota, the ameba could be demonstrated in the secretion. This patient died, and he had all the appearances that have been described. The other case was similar to, but not so severe as, the case described by Dr. Musser. The symptoms were severe if the young man permitted himself to continue exercising, or to labor and work, even intellectual work. If he remained in the hospital under careful diet and rest, the symptoms would not be severe and the dysenteric discharges would nearly cease. The discharges were examined by Dr. Westbrook and no amebic germs could be found. There were no agglutination phenomena like those reported. No adequate cause for infective symptoms could be demonstrated. I speak of these cases because it is quite possible that the information may be of some value. They will be reported elsewhere more fully.

Col. A. A. Woodhull, U. S. A.—I can add nothing to what Dr. Flexner has said. The statements that he has made in such a complimentary way are of service not only to the army but to medicine at large. My own duties in Manila were purely administrative, having no direct relation to clinical medicine. One can not work with both hands under those conditions. We suffer from a great deal of dysentery and other affections peculiar to the tropics. In a general way we found that it was desirable that the severe cases should be sent out of the country because of the fact that there was a general tendency to reaction. But that is a little apart from this discussion. There is nothing I can properly say that will add to the professional knowledge on this subject beyond what has been stated by Dr. Flexner, Dr. Osler, and others.

Dr. Franklin E. Murphy, Kansas City, Mo.—While listening to the report of Dr. Flexner I received the impression that he is not ascribing such an important part, in the production of so-called tropical dysentery, to the ameba coli as is taught by Dr. Osler and others who have studied the disease. I am extremely interested in this subject for the reason that in our locality, Kansas City, in the same latitude as Philadelphia, I have seen three cases of amebic dysentery. The first case I saw seven years ago. The case was reported in The Journal. The patient lived continuously in Kansas City for more than eight years prior to the attack and in these eight years had not been ten miles from home. I have since seen two other cases. One a patient who lived about fifty miles west from Kansas City, in Kansas, was suspected to have a pulmonary abscess consequent to pneumonia. A carefully taken history showed, however, chronic dysentery; later, symptoms of sepsis; then was found a large area of dulness at the base of the right lung, and after a time expectoration of much pus. Amebæ were repeatedly demonstrated in this pus. This patient had never been below this latitude.

The third case was that of a man who lived in Kansas City for twelve years, and who, in that time, had never been out of the city. Amebæ corresponding accurately with all descriptions given were repeatedly found in the bowel discharges. I rise, merely, to report to the Section the occurrence of amebic dysentery in an inland city so far north as the latitude of Kansas City.

Dr. V. C. Vaughan, Ann Arbor—I would like to ask Dr. Flexner if he has had an opportunity to make a bacteriological study of the so-called bloody flux that is sometimes quite prevalent in the Southern states. I have seen epidemics of this disease in Missouri and one or two small epidemics in Michigan. But the disease is very rare as far north as the last-mentioned state. A few years ago I made a bacteriological study of several cases of this disease and could find only the colon bacillus. However, this study was not very thoroughly carried out, and I have not since had an opportunity to pursue it further. In the camps in the Southern states during 1898 there were a great many cases of acute dysentery in which the patients passed considerable quantities of blood. These cases were easily amenable to treatment, and usually recovered after the administration of a few doses of castor-oil. In going over the sick reports furnished by regimental and other army surgeons I was struck by the fact that among the troops that remained in the United States in 1898 there were very few cases of chronic dysentery. On the other hand, during the Santiago campaign I saw a great many cases of dysentery, and these differed wholly from those which I had previously observed in this country. In Cuba the men with dysentery passed but little blood. They had many copious stools, and rapidly wasted away, becoming exhausted physically and apathetic mentally. I was also impressed with the fact that many of these patients recovered under the hypodermic administration of strychnia. I saw a great many men suffering with this disease who were apparently *in articulo mortis*, but who recovered if the heart was kept going by the use of strychnia. I think there were few cases of amebic dysentery among the soldiers who participated in the Santiago campaign.

Dr. J. H. Wilson, Beaver, Pa.—A member of the 10th Pennsylvania Volunteers, came under my care in August, 1899, in whom the disease was progressive. He died April 20, 1900. The clinical type was as Dr. Musser has stated. The attack presented the appearances as related in the paper from the beginning to the end of the disease. There was no epithelium on the tongue; there was no blood in the stools; there was no pain, nor any elevation of temperature—which is a point that has not been mentioned by the speakers. During the greater part of the time the temperature was subnormal. Emaciation was progressive and went on to the last extreme, and the patient died from exhaustion. There was never any pain or tenesmus and no evidences of sphacelation of the mucous membrance.

Dr. Simon Flexner—Replying to Dr. Osler's question: I think it highly probable that the acute forms of the disease which we encountered may agree with those arising under the conditions mentioned by him. It is desirable that from now on all acute outbreaks of the disease should be examined in reference to their bacteriology and also to their blood reactions. The latter test will often be possible when the bacteriological examination is for one reason or another impracticable. I shall be happy to supply cultures of the bacillus to anyone desiring to carry out the tests. In regard to Dr. Bridge's question I see no objection to a belief in the existence of a double typhoid and dysenteric injection. I have, however, not encountered such an instance. Under such circumstances the agglutination phenomena might at first be very puzzling. Then it is to be borne in mind that the typhoid reaction may persist after recovery from typhoid fever, after which a dysenteric infection may be acquired. Dr. Hunter's question regarding the duality or multiplicity of tropical dysentery is answered in my paper. Abscess of the liver would appear to be common only in the amebic disease. It was not encountered in the acute or chronic bacillary cases studied.

Dr. J. T. Musser.—There was an absence of fever; indeed, the temperature was subnormal throughout. I wish to lay stress on the method of diagnosis formulated by Dr. Flexner, the agglutination method. I also wish to emphasize the fact he has referred to, namely the absence of secondary infection in other parts of the body.

CASE OF MALIGNANT ENDOCARDITIS WITH RECOVERY.*

N. S. DAVIS, JR., A.M., M.D.
Professor Principles and Practice of Medicine, Northwestern University, etc.
CHICAGO.

D. McD., a locomotive fireman, aged 25, entered Mercy Hospital Dec. 4, 1899. His family history was excellent, and habits were good. He had la grippe seven years ago. During the past year he had suffered from frequent headaches. These occurred almost daily during the preceding month. The pain was severe, and lasted several hours; at times it came twice daily. During the same time he suffered from gastric distress, coming on a few minutes after eating and lasting one or two hours. Gaseous and acid eructations were frequent. For four or five months vomiting occurred soon after several meals, especially if work was undertaken then. His bowels were constipated. Hurried movements caused slight breathlessness. He had noticed at irregular intervals palpitation of the heart. For a year he had not had the endurance which he formerly possessed. His general nutrition was good, his tongue slightly coated, and breath heavy. Physical examination of thoracic organs revealed nothing. The liver and spleen were normal in size. There was slight tenderness in the epigastrium, but no distention of the abdomen.

He did not vomit after he entered the hospital, but the headaches persisted. Symptoms of gastric indigestion lessened, and his bowels were kept fairly regular. His pulse and temperature were normal for a week. On the afternoon of December 11, the former was 84 and the latter 99.2 F. Two days later the afternoon temperature was a little over 100. On the 16th of the month it was 101.4, and on the 18th, 103. His headaches were severe up to this time. During the following week they lessened and finally disappeared. His temperature resembled that of typhoid. It was usually from 101.6 to 102 in the morning, and from 103 to 103.6 in the afternoon. His face was not flushed; abdomen not tympanitic, and there were no rosy spots. The spleen was very moderately enlarged. He had little appetite, and was placed on a milk diet. At no time during the course of his illness could plasmodia be found in his blood, and it caused no clumping when Widal's reaction was attempted. On the 24th of the month he had a slight nosebleed. On the 26th the morning temperature became 99. A few days later in the afternoon rise became less and of shorter duration. For instance, on Jan. 1, his temperature was not above 99 from 4 a. m. to 2 p. m., and not above 100.5 from 3 p. m. to 7 p. m. A 8 p. m. it reached its maximum, 101.2.

About a week before this I observed that the first sound of the heart was peculiarly feeble, so weak in fact as to be almost inaudible. The next day it was not quite so feeble, but near the left margin of the sternum, opposite the second intercostal space, a roughness of the second sound was every evident. This gradually became more intense, and finally a clear rough murmur could be heard. It was audible in an area about as large as a silver dollar. No thrill could be felt, and the heart was not enlarged. His pulse was of medium size, soft, and showed from 84 to 96 heart-beats per minute. His temperature was low, except for a short time in the afternoon, when it sometimes reached 102, and always 101.5. On January 6, his temperature was 100.4 at 8:30 a. m.; 101 at 2 p. m. At 1:50 p. m. he had a severe chill, which lasted twenty minutes. His temperature rose to 104.5 at 6 p. m. During the evening he sweat profusely. At 9:45 the next morning he had a similar chill. His temperature at 10 was 104, and it reached 105 at 4 p. m. Profuse diaphoresis followed the chill and fever. On the 8th he had no chill, but on the 9th he felt cold at noon, when his temperature was 103.4. Up to this time he had been bathed as typhoid patients are. He had become greatly emaciated and very feeble. Recovery seemed very improbable. Daily inunctions of unguentum Credé were begun. He had no more chills and his fever steadily lessened. On the 15th his temperature was 99.4 at 5 a. m., 97.6 at noon, and 101 at 10 p. m. The inunctions were discontinued. Two days later he had another chill and his temperature rose to 103. The following days it was 102.2 at 8 a. m., 103.5 at noon, and 102.6 at 4 p. m. Daily applications of the ointment were again commenced. After January 20, his temperature did not exceed, and rarely reached, 100. He steadily improved. He was able to take more nourishment and gained strength rapidly. The heart murmur continued, but was not so rough in quality as at first. Although his temperature had been normal for a week, on January 31 he awoke with fever. It was then 102.8; at 10.30 a. m., 101.4; at 1:30 p. m., 102.2; but the following day it was again normal. There was no apparent reason for this rise of temperature. For ten days the thermometer rarely registered an oral temperature of more than 98. On February 20, after he had been sitting up for some days, his left leg became moderately edamatous to the hip. There was pain and tenderness in the calf of that leg. By March 4 all evidences of this phlebitis was gone. On the 6th he was discharged from the hospital. He had nearly regained his weight. He felt perfectly well, but lacked endurance. Slow walking did not quicken his heart. Its sounds were normal, except that the second at the base was slightly rough. It would be called an impurity rather than a murmur. His digestion was good. During his illness his urine was examined frequently; it contained a trace of albumin only once. A positive diazo-reaction was obtained several times. On January 1, his blood contained 3,860,000 red corpuscles and 5200 white. March 5, it contained 5,020,000 red and 6800 white. At no time did he have pulmonary symptoms.

---

* Presented to the Section on Practice of Medicine, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

When this patient first entered the hospital a diagnosis of gastroenteritis was made. When his fever began typhoid was feared, but except for the continued high temperature there were no symptoms of it. The possibility of malignant endocarditis was considered soon after the pyrexia developed, and I felt that the diagnosis was confirmed when the persistent cardiac murmur was discovered.

The history of this case is that of an acute infection of a severe type, in the course of which a heart murmur persistent and characteristic of aortic regurgitation developed. The fever was not typhoid, malarial, tubercular, nor could a source of sepsis be readily found. The course of fever and its severity made the case during the first of his illness resemble those cases of acute endocarditis which are described as typhoidal. Later the type changed, and it became distinctly septic. Such a change of type I have seen in several other instances.

A hard and fast line can not be drawn between simple and malignant endocarditis. Anatomically they are identical. Those cases in which high fever seems to originate from endocarditis are usually called malignant.

In this case there were none of the usual sources of infection, such as pneumonia, abscess, suppurating wounds, gonorrhea, or middle-ear disease, and it was not preceded by any typical infection. Is it not possible that the chronic gastritis may have made infection possible? This recalls to my mind another case seen by me several times in consultation, in which severe subacute enteritis seemed to be the channel through which infection occurred. Intense putrefaction of the contents of the intestines lasted for some weeks. It was accompanied by persistent fever of moderate grade, which was intensified whenever the putrefaction was. The patient had a chronic valvular disease of the heart, which was well compensated. During his long illness his physician, who had attended him for many years, noticed no changes in the character of the physical signs of heart disease. Nor did his heart or the murmurs change while I saw him. The existence of malignant endocarditis was suspected or thought possible, but could not be demonstrated until near the end of life, when embolism in many places and finally a rapid enfeeblement of the heart made it evident. In this case no wound or channel through which infection was likely to occur could be found, unless the intestinal disorder, which was chiefly characterized by intense putrefaction in the fecal mass, afforded it.

It has been my lot to see numerous cases of malignant endocarditis. This is the first in which I have seen recovery.

In 1888 Sansom[1] described a case. The evidence of chronic valvular disease did not disappear, but septic infection did. This case was treated with sulphocarbolate of zinc.

Pye-Smith[2] reported a case of recovery from ulcerative endocarditis, in which emboli had been observed in various arteries.

James Finlayson[3] reported an attack of ulcerative endocarditis in a boy, aged 10 years, ending in recovery. The case presented an alarming feature in the frequent occurrence of paroxysms of pyrexia. During these paroxysms, however, no rigors could be recognized. The patient, having rheumatic disease, was first treated by the usual antirheumatic remedies. When the paroxysms of high fever developed, quinin was administered in large doses. After six months the patient was dismissed from the hospital as convalescent, and a month later was reported quite well, active in his limbs, free from cardiac symptoms and gaining flesh.

Dr. Sainsbury[4] reported a case of ulcerative endocarditis in a boy, aged 13 years, cured by antistreptococcus serum. The cardiac dulness began in the first left intercostal space and extended to the right sternal border. The heart's apex-beat was in the fifth space, four inches to the left of the midsternal line. There was a well-marked thrill and a double-murmur at the apex. The liver and spleen were not palpable below the costal margin. The patient was admitted to the hospital and 15 grains of salicylate of soda were administered every two hours in a mixture. Then treatment with liquor hydrargyri perchloridi was commenced. The boy grew languid and took food badly. After about two months of treatment 20 c.c. of antistreptococcus serum was injected. During the next eight days 10 c.c. were injected four times. The area of cardiac dulness became again normal, and the heart's apex-beat well within the nipple line. Examination of the blood showed no streptococci, five days later another 10 c.c. of serum was injected. This was followed by marked improvement, and a week later the patient was able to be out.

A case of ulcerative endocarditis successfully treated by antistreptococcus serum is reported by J. W. Washburn.[5] The patient, a female, aged 22, came under observation a few days after the commencement of the illness. During the first seven weeks she suffered from an ill-defined septicemia, without any local manifestation of the disease. Up to the time when serum was first injected she was progressively losing ground, and a few days before the commencement of the injection the pulmonary valve became affected. The result of the treatment was most satisfactory. At the end of five weeks injections were given every other day instead of daily.

Dr. Margaret Dunn (Pearse)[6] records the case of a girl, 16 years old, who was also treated with antistreptococcus serum.

Moritz[7] reports a case of ulcerative endocarditis cured by antistaphylococcus serum. The patient, aged 22 years, had had gonorrhea and cystitis eight months previously. At the time of the onset of the malady no gonococci could be discovered. A musical murmur was heard, and the diagnosis of malignant endocarditis seemed to be beyond doubt. Moritz decided to try antistaphylococcus serum, because a previous case had shown after death the presence of the staphylococcus albus and aureus. The acute symptoms disappeared after six injections of 5 c.c. of the serum. The temperature was normal about six weeks later. Metastatic inflammation was observed in the right calf and in the left ankle after two of these injections, but no suppuration occurred.

It is difficult to determine from the scattered literature of the subject what is the mortality of malignant endocarditis. Occasionally cases such as these are recorded. The much larger number of fatal cases are not. The mortality is high, and the malady is rightly regarded as almost invariably fatal.

It is not possible from these few cases to discuss treatment satisfactorily. It is a noticeable fact that the majority were treated with remedies believed to have some specific value in combating streptococcus or staphylococcus infection.

DISCUSSION FOLLOWING SYMPOSIUM ON ARTHRITIS.

Dr. F. A. Packard, Philadelphia—At the present time rheumatism is a term used to cover much of our ignorance. It is now applied to almost any painful affection, such as neuritis, myositis, pleuritis and various forms of endocarditis, even where there is nothing in the history of the case to warrant the diagnosis of rheumatism. Rheumatism should not be the diagnosis, simply because there is present trouble with the endocardium or an affection of any one structure. The occurrence of endocarditis, pericarditis or inflammation of other serous membranes does not warrant the diagnosis of rheumatism. These occur from a variety of infections. If we diagnosticate various lesions as rheumatic we are in danger of covering our heads in the sand and ceasing to look for ultimate etiological factors in each particular case. A proper definition of acute articular rheumatism would, I think, be as follows: Acute rheumatism is a well-defined series of morbid signs and symptoms produced by an etiological factor at the present time not definitely known, but probably of micro-organismal origin. The process is characterized by a tendency to attack serous membranes, notably the heart and endocardium.

It seems to me that in arthritic diseases there is quite a distinct series of gradations, each being separate and distinct, a regular and progressive series leading from acute articular rheumatism to the various arthropathies. Starting from, 1, acute articular rheumatism, one can pass to, 2, the acute arthritis occurring in the course of well-recognized infections, such as scarlet fever and gonorrhea; 3, chronic infectious arthritis, such as is especially seen in children and young adults, in which we can not always find the seat of primary infection; 4, somewhat allied to these are cases of arthritis deformans; here there is a strong likelihood that the infectious nature of the disease will be in a short time, absolutely proven; as Dr. Kelly pointed out, in the disease there are various atrophic changes, probably due to lesions of the central nervous system, produced by absorption of toxins from the infected joints; 5, the arthritis of gout; 6, midway between rheumatoid arthritis and the changes in gout might be placed the spinal arthropathies, although these are apparently at first purely degenerative changes.

Given a case of endocarditis with growing pains, why should we call it a case of rheumatic endocarditis? There is no possible reason, unless we accept the frequency of the occurrence of endocarditis in acute rheumatism as a proof of the relation. I believe that in pleurisy it is a great mistake to speak of rheumatic pleurisy unless it is due to tuberculous infection or is due to extension from the underlying lung. As with endocarditis, so in the case of pleurisy, the pleural serous membrane can be involved in any infection, and the so-called rheumatic pleurisy is in reality a mild infection of the pleura.

Rheumatism is not a nervous disease; the only possible reason for thinking of the nervous system in connection with it is because of the atrophies occurring in the neighborhood of the inflamed joint. Regarding the lactic-acid theory, because Richardson injected lactic acid in animals and found change in the endocardium, this theory held sway for a long time. It is now abandoned. The excess of lactic acid in rheumatism is an effect of the disease and may possibly produce some of the symptoms secondarily. Personally I believe that acute articular rheumatism is an infectious process, probably not caused by one particular organism, but by various organisms. Access to parts may be obtained through various points of entrance, that more frequently employed being the mucous membrane of the throat. I would finally make a plea for a more careful nomenclature, in regard to all of the group of lesions of joints, serous membranes and fibrous tissues to which the term "rheumatic" is now so frequently applied.

Dr. J. H. Musser, Philadelphia—I have been well repaid for my attendance here to-day. I am somewhat in a quandary in regard to the classification of rheumatism. I feel that Dr. Packard's classification is a satisfactory, provisional one. In my own mind I am accustomed to divide joint lesions in accordance with the form of infection, which is causal. We must bear in mind that a number of joint cases have undoubtedly a toxic or chemical origin, not only the toxemia of gout, but also that due to diseases of the gastrointestinal tract. I should like to lay particular stress on the number of cases of toxic origin frequently associated with the skin lesions which are also seen in rheumatism; in this broad class of cases it is quite common to find forms of erythema associated with arthritis which are manifestations of gastro-intestinal disorder as indicated by the symptoms as well as by a physical and chemical examination of the gastro-intestinal secretions.

Dr. J. M. Anders, Philadelphia—Rheumatism is unquestionably an infectious disease, although the infectious agent has not yet been discovered. The leading complications, endocarditis and pericarditis, are always infectious, and, I believe, they will be shown to be due to a toxin or the micro-organism of the disease. The subject of the relation of chorea and rheumatism is of special interest. I find myself in agreement with Dr. Burr when he states that they are not etiologically related, even though, as he stated, acute rheumatic manifestations may precede an attack of chorea. In my experience chorea occurs quite commonly in persons hereditarily predisposed to rheumatism. While, therefore, not in accord with the view that these diseases are specially related, it should be remembered that the period of greatest liability to rheumatism is between the years 30 and 40, and for chorea, probably between the 10th and 15th years. Both are frequently occurring affections. I believe that rheumatic attacks rarely either immediately precede or follow on chorea. On the other hand, in a much larger percentage of cases rheumatism follows chorea at a more remote period. I was glad to hear this point emphasized. He also said correctly that the endocarditis of chorea is not necessarily a rheumatic endocarditis. Endocarditis is an effect and not a cause of chorea. The diagnosis of endocarditis in connection with chorea is confessedly difficult. I think it is going too far to assume that in all cases of chorea in which endocardial murmur occurs it is dependent on an endocarditis; it may be functional. In some of my cases the heart murmur has disappeared after the chorea ran its course. Chorea is not a febrile affection, and when fever develops in connection with the presence of a murmur then we may be justified in making a diagnosis of complicating acute endocarditis. On the other hand, rheumatism is a febrile disease. Here the diagnosis of acute endocarditis as a complication rests upon the fever, a heart murmur, and a slight increase in the area of cardiac dulness toward the left, due to dilatation of the left ventricle. In a paper published a few years ago I analyzed the complications of erysipelas, and of the total number—over 200—I found acute rheumatism to be the most frequent complication, next to abscesses. The danger of mistaking acute articular rheumatism for other forms of multiple arthritis occurring secondarily to acute infectious processes, is great. It should always be borne in mind in attempting a diagnosis of rheumatism that it is, as a rule, a primary affection. In the cases in which the rheumatism is itself secondary to other infective disease it is frequently impossible to differentiate it. Still, I should like to emphasize two points: 1, secondary acute rheumatism is a rare affection, rheumatism being usually a primary disease; 2, the nature of the primary affection should be noted for the reason that it occurs more commonly after certain infectious diseases than after others. It is not uncommon after erysipelas, and I also believe that acute rheumatism does occur, though rarely, during convalescence from scarlet fever.

It is lamentable to note the number of cases of osteomyelitis that are confounded with acute rheumatism. Osteomyelitis is sometimes a subacute affection, or develops more gradually than is usual, and if not recognized early and properly treated produces marked destructive changes. The differential diagnosis between these affections is important. In osteomyelitis, as in rheumatism, we have redness, swelling and tumefaction. While these symptoms may extend clear to the joint implicated, they do not involve the articular surfaces in the early stages of the affection at least. In osteomyelitis the bone is affected and, when making bilateral pressure with the thumb and finger, there is great tenderness, not over the joint, but immediately above or below it. In a case I saw in consultation in the early stage of the affection I could flex and extend the leg gently without causing additional pain; that could not have been done in a case of acute rheumatism. This, of course, applies only to the early stages of the affection. Septic osteitis is usually a mono-articular affection; whereas, rheumatism is a polyarthritis, as a rule; at all events, acute rheumatism in the early stages is almost always a polyarthritis. Yet, one should remember that some of the joints implicated in rheumatism may be so slightly involved as to give rise to little suffering and hence may be entirely overlooked; such cases are often regarded as mono-articular from the start. It is also to be remembered that osteomyelitis may be multiple; this point is important. Fever and joint symptoms are more profound in septic osteitis than in acute rheumatism, except in the subacute cases. Sweats are less common than in acute rheumatism. The therapeutic test with salicylic acid also aids in making a differential diagnosis. It positively relieves the pain in acute rheumatism, but it has no effect in osteomyelitis. I emphasize the differential diagnosis between these two affections because, although they would appear to be surgical from the standpoint of treatment, yet it is the physician who, as a rule, is first called to see them. The question of the prevention of the cardiac disturbances in acute rheumatism is interesting. Not to detain the Section longer I will state that my own rule is to employ the combined salicylic acid and alkaline treatment. It has seemed to me that this method does obviate the development of cardiac complications, the prophylactic influence being ascribable to the alkalies. Dr. Kelly has given us a clear and elegant exposition of the pathogenesis of rheumatoid arthritis.

Dr. Charles G. Stockton, Buffalo.—There seems to be a lack of certainty in considering the ground now open for discussion on the question of arthritic diseases; but the consensus of opinion seems to be that they are infectious diseases; no one in the discussion to-day has been heard to state otherwise; and it has been admitted that it probably depends on no one infection. It has also been stated that we should not regard endocarditis as necessarily the result of rheumatism. Now, endocarditis is the result of infection. Of course nearly all admit a small group of infections which produce in individuals acute affections that have a rather definite clinical history and are relieved by the administration of salicylates; and this group is named rheumatism. We agree to speak of rheumatism as a specific disease; perhaps it is. If we could regard rheumatism as depending on one influence, it would simplify matters. Have we reached that point? I think we have not. So far as we understand acute rheumatism to-day it is not always due to one particular infection. Take the other extreme and speak of chronic joint affections; there are unquestionable reasons for believing that they depend on neuropathic conditions. We may get that extreme in the Charcot's joint. Dr. Kelly has presented all we know, and as well as it could be presented, when he used the expression "neurotrophic infections." When he referred to "neurotrophic infections" I did not understand; but as he further demonstrated his position I could see that he meant that the weakness of certain structures permitted infection to find place. I think that is a reasonable position to hold. It is a position parallel to that taken in the admirable paper read yesterday by Dr. Preble. There are conditions that produce different results in different individuals, depending on the lowered resistance of certain parts. Having reached such a point of view, we may go back further and state that there are certain conditions in certain individuals called "diatheses" which influence the development of arthritic conditions. To admit some other influence besides the action of infection in producing acute and chronic rheumatism seems to be necessary. Diatheses represent some of these influences.

Dr. Louis Faugeres Bishop, New York City—I believe there is a disorder of the chemistry of the body as well as infection. I believe that there are disorders of the powers of nutrition besides infection. By classifying these disorders into certain groups we can get a better idea of arthritic affections. Take that which is most striking, acute rheumatism; this is undoubtedly a specific infectious disease. Certainly, in the spring of the year the hospital wards are filled with cases of an acute rheumatism; a disease that attacks young adults, coming on suddenly with temperature and with pain in a joint, that spreads to other joints of the patient; a disease with a tendency to endocarditis. Toward the middle of the summer many of these cases have entirely recovered without any tendency to recurrences. Such a patient may go the rest of his life without another attack of rheumatism. That is acute rheumatism and represents an infection. On the other hand, gout is a disorder of the chemistry of the body whereby insoluble urates replace soluble urates in the system. I believe that much stated about uric acid in relation to gout is a great humbug. Gout is a complex disorder of the body chemistry.

Again, there are disorders of the tissues of the body due to trophic disturbances. The nervous system is so perfect in action and so little liable to disorder that we do not realize how dependent the nutrition of the body is on the nervous system. I lately saw a case in which the trophic influence was cut off, showing how important this is. A patient developed myelitis of the lower end of the cord. In the course of a few days he had excavated ulcers over the sacrum. The myelitis cleared up and repair took place in the course of a few months. That is an extreme instance of trophic change. The nervous system sometimes becomes disordered and disturbed through other affections; for instance, in persons who have undergone shock. The general trophic powers of the nervous system are disturbed and there may be developed arthritis deformans. As the Doctor has stated in his paper on this disease, there is probably some disturbance in the trophic centers that control the joints.

Now, having clearly stated that there is an infectious articular rheumatism, that there is a disturbance of the chemistr of the body and that there are neuropathic disturbances, then to clearly define the various arthritic cases we must consider that there is often more than one of the causes existing at the same time. If, also, we get a clear understanding of the various blood infections and if we remember that the sick are specially liable to the development of these poisons, we can explain a great many symptoms by secondary infection in the acute rheumatism, in gout, or in neuropathic trophic conditions. In reference to chorea, it would seem that, like rheumatism, it has been too definitely defined. We have Sydenham's chorea, which is fairly a well-defined disease like acute rheumatism; but there are other forms of choreic movements. It sems to me that chorea major is a different disease, and probably a disease due to some more serious infection. We have choreic movements due to other diseases than chorea: among these are septic infections. For instance, I have seen choreic movements develop after measles, having probably no connection with ordinary chorea; it was an entirely different condition. Although I have examined many hundred cases of chorea and discovered many murmurs, I believe that only a few of them were due to an endocarditis. I do not believe that chorea and rheumatism are the same disease. Rheumatism is confused with other infections, and chorea often complicates these other affections.

Dr. G. W. McCaskey, Fort Wayne—I protest against the term rheumatism, except when applied to the definite clinical picture which we all recognize. We should drop that indefinite term in a large group of cases which have no connection with rheumatism. I wish to refer to the subject of arthritis deformans. I do not know whether to use the term infection or not; I think that it is a toxemia, the toxin resulting from some sort of germ infection gaining access to the blood and so affecting the tissues with which it comes in contact. The origin of the poison is, I think, most probably from the gastrointestinal tract. I may say in this connection that I have not found a single case in which there was no evidence of gastrointestinal disturbance or toxemia from this source. While the treatment is, perhaps, outside the scope of this discussion, yet I wish to refer to one experiment recently made by myself with cataphoresis. The negative electrode was placed over the forehead and both hands were immersed in a saturated solution of iodid of potassium in which the positive pole was placed; the current was then turned on as strong as the patient could bear it.

Dr. S. Solis-Cohen, Philadelphia—Arthritis deformans is still something of a scrap-bag. It must further be subdivided into several classes. Acute cases chiefly affect the large joints, while the chronic cases chiefly affect the small joints. In the chronic cases there are at least two classes, those in which a spindle-shaped deformity develops and those in which lateral deformity results from exostoses. If infection has to do with arthritis deformans it is more probable that it will be found in the acute than in the chronic cases. The latter probably depend more largely on metabolic error. If Dr. Kelly will modify his formula and substitute for infectious trophoneurosis, the term toxic trophoneurosis we shall all agree with him. There is one drug of much value. That drug is the tincture of the chlorid of iron. It must be given freely and frequently. By a simple pharmaceutical device, the use of ammonium citrate may be combined with sodium salicylate; this combination seems especially useful in anemic persons and in recurrent and lingering cases. To prevent the cardiac complications, we must give an alkaline course pushed quickly until the urine becomes and remains distinctly alkaline. Why, I do not know. Methyl salicylate—oil of birch or oil of wintergreen—can sometimes be given when other salicylates are not well borne. It is a question of the individual and of care in administration. Locally these oils are sometimes very useful.

Dr. D. Riesman—Regarding the treatment of rheumatoid arthritis I would recall to the Section a case which I reported at the Philadelphia meeting three years ago. It was a young woman who had been unable to stand or walk for seventeen months on account of rheumatoid arthritis involving, among other joints, also the knees and ankles. The knees were flexed, but by the use of extension, such as is employed for fractured femur, the legs were gradually straightened out. The apparatus was on altogether sixteen weeks. The disease was arrested and the patient was able to walk and ride on the bicycle, although for many months distinct grating in the joints persisted. I am convinced that if extension had not been employed she would have been hopelessly crippled despite the arrest of the disease. The treatment I employ in acute articular rheumatism is salicylate of sodium in large doses, combined, if the heart shows any signs of involvement, with the alkalies; and in that case the latter are given in large doses until the urine is alkaline in reaction, after which the dose is reduced. The diet consists of milk and lemonade, and the patient is kept between blankets. With respect to the etiology of rheumatism the speakers seem all to be agreed that it is an infectious disease. I believe that we shall find not only that it is an infectious disease, but that the typical disease is due to one species of microörganism—and to one alone.

Dr. James J. Walsh.—It is interesting to note that rheumatic endocarditis always occurs in the left heart. The blood flowing through the left heart has just come from the lungs and is freshly aerated. If the supposed microbe of rheumatism be in the blood-stream it is just at this moment after its recent exposure to the oxygen of the air that it may be considered to have taken on new vitality. On the other hand the comparative absence of oxygen in the venous blood may account for the fact that the right heart is so seldom affected. The aerobic germ of rheumatism is, in its passage throughout the right heart, in a condition of lowered vitality. The connection between rheumatism and chorea has been a matter of a great deal of dispute. One lesion is constantly found at the autopsy of chorea cases. It is a chronic endocarditis. Here seems to be the point where chorea and rheumatism touch. Chorea as we see it is really a nervous disease. Its manifestations may very well be due to an insufficient blood-supply to the motor cortex. The reason for this insufficient blood-supply is the chronic endocarditis that has been noted as occurring so constantly. The affected heart does its work very well until under the stress of over-work, over-study, sudden fright or great emotion, an excessive call is made on its energy. A certain amount of incompetency develops and in the growing child with extreme sensitive nerve cells the disturbance of circulation is first noted by its action on the motor cortex. The endocarditis that leads to this disturbance of circulation is due to a preceding attack of rheumatism, or some other infectious disease. It is well known that chorea may follow almost any of the infectious diseases. Its greater frequency after rheumatism is only due to the fact that in childhood particularly, rheumatism almost never leaves the heart unaffected. The attack of rheumatism which caused the endocarditis may have been almost latent, may have been concealed under the term "growing pains," or may have been a primary rheumatic endocarditis without any arthritic manifestations. The reason why patients who have had chorea have subsequent attacks of rheumatism is that they had rheumatism before they had their chorea, and one attack of rheumatism predisposes to subsequent attacks.

Dr. DeLancey Rochester—In reference to the treatment of acute rheumatism, the use of iron is of the utmost importance. Here there is a tremendous anemia that should not be neglected. The pyrophosphate of iron is of value given in doses of 8 to 15 grains; little doses are of no value. The tincture of the chlorid of iron is of great value in doses of 15 to 30 minims. I believe that no treatment can prevent heart infection. I believe, moreover, in the rest in bed treatment, which tends to prevent dilatation of the heart. Strychnin given throughout the disease is of great value. The bowels should be kept freely open by the use of Rochelle salts. Large doses of sodium salicylate, frequently repeated, should be administered day and night.

Dr. A. O. J. Kelly—In the treatment of several cases of arthritis deformans, I have observed considerable good result from the use of superheated dry air. I recall one case in particular, that of a middle-aged woman, who, in August last, was admitted to the medical wards of the Hospital of the University of Pennsylvania to the service of Dr. Musser. She had to be carried in, as practically all the joints of her extremities were implicated, more especially the joints of her hands and feet. In addition to repeated treatments with hot air she was given some alterative medication and a full nutritious diet. After treatment lasting for a couple of months, she left the hospital able to walk without a cane and able to do fine embroidery. That the desired results be attained, it is essential to bear in mind that the treatment with hot air must be persisted in for some time even if a dozen or more applications seem ineffectual. It may even be observed that in a few cases each of the early treatments seems to be followed by an aggravation of the pain; the mobility of the joints is, however, almost always increased. In certain cases of acute articular rheumatism this treatment is also efficacious. It finds it especial range of usefulness, however, in those cases that seemingly commence acutely with implication of many joints, but which, instead of subsiding as do the cases ordinarily, pass on to a subacute stage with especial localization of the disease in one joint, usually one of the larger joints. In the majority of cases of acute rheumatism, the first essential is to bring the system rapidly under the influence of the salicylates. Personally, particularly in persons with sensitive stomachs, I prefer the salicylate of strontium. In many cases the pure salicylic acid administered in milk will be found most effectual.

EXTERNAL DRAINAGE OF LUNG CAVITIES.*

LE MOYNE WILLS, M.D.

LOS ANGELES, CAL.

The subject to which I wish to call your attention is one much neglected, though very near to us all, especially to those of us who live in the regions to which tuberculous patients are most frequently sent in all stages of the disease.

Just why abscesses and cavities in the lungs should be allowed to run their course of breakdown and produce infection of the other lung and a pyemic condition of the system is hard to explain in these days of exploitation in all parts of the human body. It is partly due to the timidity of the physician in recommending, and in operating for, the relief of the suppurative process as elsewhere, but chiefly to the reluctance of the patient to submit to operation when there is yet time to do good by such interference.

Of course it would not be good surgery to subject a patient in the last stages of his disease to such hazard with such a very small chance for betterment. When satisfied that we have to deal with a septic condition, due to inadequate drainage by the bronchus and in order to save a patient's strength and life, then I claim it to be good conservative surgery of the most progressive type to drain cavities externally. I hope to be able to sustain my point by two cases operated on by a colleague and myself for the relief of this condition. Both these patients were failing rapidly from fever and sepsis, and each had one good lung, the other seriously damaged, and both were in fairly good condition for operation and willing and anxious to undergo anything that promised relief for their unfortunate condition.

From an elaborate series of experiments on rabbits, reported to the Medical Society of the State of California in 1892, I satisfied myself that the resistance of the pleura was much greater than is usually supposed, and that the lungs could be operated on with much less danger than authorities had formerly taught. I chose this animal for experimental work because of its lack of vitality, which diminished the chances of recovery, and because it would probably follow that the same operation on human lungs would be more so, if the operation on the rabbit's lung was successful. Until 2½ years ago I could not find a patient who would submit to such an operation as I wish to report to you. Several, however, talked of it, but always backed out as the time agreed on drew near. In fact, my first patient went to the hospital for the operation, grew somewhat better temporarily, then declined it and left. Afterward, however, he grew steadily worse, and in six months returned for operation. This was in March, 1898.

History—H. H. H., aged 45, unmarried, was born in California. He was 5 ft., 9 in. in height, and his usual weight ranged from 175 to 200 lbs. He was a ranchman and liveryman, a man of fine physique, with red hair, large chest, was accustomed to all kinds of labor and had been a vaquero. He had comparatively dissipated habits, no personal history of syphilis, and no history of tubercular disease in his immediate family, nor, in fact, among his more remote ancestors. His father and mother were living, aged 75 and 70 respectively, and he had brothers and sisters all well and vigorous, of good size and physical strength.

In October, 1896, having been unfortunate in farming operations, he came to the city, did not find work, was badly lodged and fed, and rapidly ran down in flesh and strength. Then, on December 17, he presented himself with evidences of pleurisy on the left side. The salicylates were exhibited under the impression that the pleurisy was of rheumatic origin. The treatment reduced the temperature and relieved pain; however, after about a week or ten days, evidences of effusion were present within the left pleura cavity. Salicylates were continued and iodid of potassium given, and with repeated counterirritation. The effusion gradually disappeared, as well as the pain and discomfort, and the patient was to all appearances restored to health.

Believing himself to be in good physical condition, he accepted a position as foreman in charge of hydraulic placer mining operations, and this, during the winter, exposed him to all kinds of weather, and also led to constant wetting. The following August the second attack occurred, confining him to his tent for about three weeks, and during this period, according to his statement, he suffered from high temperature and pain on the side previously involved. It might be well to state here that these attacks of pleurisy were not preceded by any pain or inflammation about the joints, and so it was probably tubercular from its inception.

On August 30, 1897, the patient was brought to my office by his physician, Dr. Shorb, suffering from laryngitis, emaciation and cough. He gave the history as above, and stated that during a ride of some twenty miles, over rough mountain roads, a sudden vomiting of about 1½ pints of pus took place, and with this venting a relief of pain.

Physical Examination.—He showed marked emaciation, large frame, good chest development, and, on inspection, impaired respiratory movement of the left side—rapid breathing, his respiration being about 24 to 30 per minute. His fingernails were clubbed on the left hand and the matrix showed evidences of imperfect oxidation. On palpation, there was impaired resonance and increased vocal fremitus at the apex. The lower lobe of the left lung, at a point over the lower end of the scapula, had all the characteristic signs of cavity. There was also, in the apex, a condition either of small cavity or an area of consolidation. However, there existed no question as to the larger cavity. This latter, approximately, extended from the sixth interspace to the ninth rib, and apparently from the spinal column to the mid-axillary line.

The patient gave a history of dyspnea and orthopnea, with vomiting of from half to one pint of pus every morning. Examination of his sputum showed the presence of tubercle bacilli with elastic fibers, etc. He was induced to go to the County Hospital for an operation, and after his admission, showed marked septic symptoms, with a temperature ranging from subnormal in the morning to 101.2 in the evening; he also suffered from night sweats.

---

* Presented to the Section on Surgery and Anatomy, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Operation.—A consultation was held and resection of the ribs for external drainage of the lung cavity advised. He was put on tonic treatment and given large doses of creosote for several weeks, with such improvement in his general condition—an increase of 15 pounds in weight—that he declined operation. He remained in the hospital three months, and during this time the amount of expectoration lessened, owing to good medicinal treatment and the creosote, but the septic conditions continued. He gained in weight but not in strength. At the expiration of the three months he returned to his home in San Jacinto, a town in the San Jacinto Valley, inland, 100 miles from the coast and with an altitude of 1500 feet. He remained there until March, 1898, gradually losing ground gained by the former treatment. During the last week of this month his condition grew so serious, and he was expectorating such large quantities of pus continuously, that he came to Los Angeles for operative relief. There an interesting condition was discovered. When first admitted to the hospital, I had intended to make a resection of the seventh and eighth ribs in the posterior axillary line, but after his return an inflammatory area was noticed extending over the fifth, sixth and seventh spaces from the anterior axillary line forward to and below the left nipple, which suggested the advisability of interfering at this point instead of carrying out my original plan. It was red, painful, bacon-like, and presented all the signs of a suppurating focus. The most natural supposition, therefore, was that the abscess had ruptured into the pleural space, and was approaching the surface at this spot. The patient's general condition was bad, temperature 104, heart's action enfeebled, breathing labored and his condition demanded prompt relief.

I made my incision over the sixth rib, in the anterior axillary line, and resected a piece 1½ inches long, found the pleura thickened, the lung very much congested, and even fingered the apex of the heart; but to my chagrin, on opening the pleural cavity, I found not one drop of pus. The patient's condition was so precarious that the operation was cut as short as possible and a large rubber drainage-tube sewed in the wound. Ether was used and, though skillfully given, he almost collapsed on the table, preventing the completion of the contemplated operation, which was to resect more ribs and enter the lung cavity and establish free drainage.

He reacted fairly well, and under bold stimulation passed the eight days following the operation uneventfully, with absolutely no expectoration, though the temperature was extremely irregular. On the morning of the ninth day, the patient was almost choked by a sudden gush of pus, intensely fetid and gangrenous in odor, through the trachea into the mouth, and it also poured forth from the wound. With this free external drainage established through the incision, which continued for months, abnormal temperature instantly ceased, and it remained normal thereafter, septic symptoms only appearing when the free drainage through the incision was interfered with. The patient became so offensive that it was necessary to remove him from the general surgery ward to an isolated room. Dressings had to be changed several times daily. Irrigation with large quantities of bichlorid of mercury solution, 1/4000, were used twice daily; the patient having unusual tolerance for this germicide, derived great benefits therefrom, and never showed any poisonous results from its use. This suppurative process continued for sixteen months, gradually diminishing.

The cavity was opened externally and had a connection with the left bronchus, as evidenced by the taste of the irrigating fluids. The patient did not gain strength during the warm weather of the summer and was losing ground every day, so decided to go back to the San Jacinto Valley in September, 1898. During the summer sinuses formed in front of the incision, following the line of the ribs and cartilages forward almost to the sternum. These were opened and curetted and finally healed. He remained at home, gained strength and cared for himself. He would fill the cavities with a strong solution of $HgCl_2$ once or twice daily, by placing himself in a recumbent position, thus retaining a quart of this solution for several hours, when he would rise up and allow it to flow out through the opening in the chest wall. This he did without the knowledge and advice of his physician. The cough gradually diminished until August, 1899, when it stopped entirely, as did the expectoration.

The patient was not seen by his physicians from September, 1898, 'till December, 1899, although they heard from him at long intervals. He came to Los Angeles and was carefully examined on Dec. 13, 1899. There was absolutely no sign of cavity, only sounds of a consolidation in the left lower lobe and bronchial breathing over the left apex. He is able to work, chop wood—had put in forty acres of grain—can ride horseback, and feels better than for years. He experiences pain only when he stoops over. He has put on 75 pounds of hard, sound flesh since he first came under our care three years ago.

This operation was simply a resection of one rib—the intention was to take out two or more, but respiration was so shallow and the condition so alarming that the operation was hastily completed, a chance for drainage only being possible. After the acute congestion produced pus, the abscess in the lung ruptured in the direction of least resistance, and the pus gushed forth up through the bronchus and out of the wound in the side. Gravity drainage through the chest wall rendered coughing unnecessary.

Undoubtedly the climate and surrounding conditions had much to do with the improvement of this patient, and he might not have recovered at the County Hospital. On the other hand, he had absolutely no attention for sixteen months, other than that given by himself. The pus simply ran out through the incision, and he washed, irrigated and dressed his wounds as he had been taught and as best he could for himself. It is a remarkable case, and well worth considering, even if what was intended at the outset was not entirely carried out owing to the man's dangerous condition while being operated on. The man had bacilli in the sputum and was in a desperate condition and the beneficial effect of the strong solution of $HgCl_2$ on the suppurative process is well worth considering.

Case 2.—M. L. D., aged 30, married, by occupation a traveling salesman, for a number of years had been exposed to all sorts of weather in northwestern Iowa, poor hotel accommodations, irregular hours. His family history was negative as regards a tuberculous taint, his parents, two sisters and one brother living in good health.

He enjoyed perfect health, weighing 128 pounds on an average until two years ago, when he had an attack of pleurisy on the right side. This occurred in July, 1898, and he was laid up two or three months. His recovery was gradual and he returned to his work, but a dry, hacking cough remained with no expectoration. In April, 1899, he began to expectorate freely, and for the first time was told that his lungs were affected, tubercle bacilli being found in the sputum. He immediately went to Chicago and consulted Dr. John B. Murphy, who also found tubercle bacilli. Dr. Murphy advised against the use of nitrogen gas in his case and recommended Colorado as a health resort. The patient returned to his home in Iowa and, in the following month had a second attack of pleurisy on the same side. He was ill six weeks and convalesced slowly. This time he was expectorating freely, suffering severe pain in his right side and having night sweats. Under the judicious use of morphin the pain was controlled and he gained 14 pounds in weight before coming to California. In July, 1899, at a weight of 114 pounds, he came to Los Angeles, and put himself under the care of Dr. J. de Barth Shorb.

Physical Examination.—Inspection showed the characteristic phthisical chest. There was no evidence of increased vocal fremitus or vocal resonance, but dulness was slightly increased over both lungs. Percussion and auscultation discovered a cavity which extended from the end of the scapula as far down as the last rib and from two inches to the right of the spinal column to the mid-axillary line, on the right side. Auscultation revealed fine crepitant râles in the apices of both lungs and evidences of bronchitis. There were evidences of compression of the right lung above and in front of the cavity already mentioned. Expectoration at this time was scanty, averaging probably a teaspoonful in twenty-four hours. The temperature varied from subnormal to 103, and the patient progressively lost in weight. He was advised to submit to operation for the purpose of draining the cavity in the back at its most dependent part.

Operation.—This was performed at 9 a.m., Jan. 11, 1900, at the Good Samaritan Hospital, several physicians present, and after careful preparation for several days. Ether was the anesthetic. Section was made over the angle of the eighth and ninth ribs on the right side, three inches from and parallel to the spine. The incision was four inches long, two inches of each rib was removed forward of the angle, no vessels except those of the skin being opened, and the periosteum and nerves pushed out of the way. The patient took ether badly and I was obliged to hurry, so hastily opened the pleura and found I was just behind the posterior edge of the cavity's adhesion to the chest well. The man's condition prevented extension of the wound forward. The pleura was carefully but hastily examined and found to be perfectly healthy and smooth. An attempt was made by both of us to push the index finger into the cavity, which could be distinguished by feel, considerable force being used, but the wall was too strong, both of us being sure of its existence, though not daring to use the knife as we had intended. There was absolutely nothing in the pleural sac. The lower lobe collapsed behind and below the adhesion over the cavity to the ribs, as above noted.

Operators were much chagrined that the cavity was not opened directly as planned, but the prolongation of the operation meant death to the patient, on the table, so the pleural sac was hastily wiped out with sterile gauze and the skin wound closed with silkworm gut interrupted sutures as quickly as possible, without drainage; a thick, firm, gauze compress and dressing was applied. The intention was to operate again farther forward. The patient reacted well.

On January 17, six days after operation, the temperature was 103 F. We removed the stitches, the wound being perfectly healed and dry but the skin distended; fluctuation was noted. The skin wound was opened freely and nearly two pints of brownish, fetid pus gushed forth. On digital exploration, the finger entered directly into the lung and discovered a large cavity, location and size as diagnosed. The wound of the pleura and cavity of the lung was irrigated thoroughly with weak formalin solution and sterile water afterward, and the cavity packed with sterile gauze, the lower level of the pleural sac walled off from the general sac and pleura, washed and dressed daily as indications required. On Jan. 18, the temperature dropped to 97.5 and then went up to 98.4, and on the 19th to 99. There was much pus, but the condition was improving. On January 28, we withdrew all gauze; there was little discharge, and granulating at the bottom, the man doing well, with a pulse and temperature slightly above normal. By January 29 he was improving every day.

The bruising of the pleura by the fingers in the attempt to enter the lung cavity produced, by ulceration, the connection with the external incision desired and gave the gravity drainage sought. Undoubtedly the pleura was the better prepared for its fetid bath by the handling it received and the consequent inflammation and covering of its surface with lymph. The improvement in pulse and temperature is good evidence of this and proved the desirability of and justified the operation.

Immediately following operation, and with the establishment of drainage posteriorly, the patient's condition began to improve. His temperature went down and his appetite and strength increased. Within a month following operation there were evidences of communication of the cavity with the bronchial tubes, as shown by the coughing up of pus on three distinct occasions and the ability to taste the irrigating fluids.

Since this I regret to acknowledge that the patient has not continued to improve and there is marked evidence of involvement in other parts of the same lung, and he is losing strength and weight; but the operative wound through the chest wall into the abscess cavity is still open and discharging a very small quantity of pus.

These cases are unique in many respects: 1, from the fact that the patients had been given up to die, both being tuberculous, as demonstrated by the physical condition and by the microscope; 2, in consenting to operation; 3, in behavior under the anesthetic (ether) due to impaired respiratory power; 4, immediate improvement after operation, as to temperature, pulse, cessation of fever and cough and no expectoration of pus as soon as pus drained through the external wound; 5, while in both cases the condition prohibited the completion of operation as planned, still indirectly the purpose of operation was attained—having by interference established a point of least resistance for the abscess to rupture and discharge its contents.

These cases were very different in history, physical strength and other characteristics, the chief difference being that in the first there was a direct communication between the abscess cavity and the bronchus, and in the second case no apparent vent existed at all, and in each case the patient was dying as a result of absorption of septic matter, and prompt surgical interference was suggested as the only means of relief. In each septic symptoms ceased as soon as external drainage was secured.

In the first case reported the condition was not one of empyema, because there was absolutely no pus in the pleural space when it was opened, and not until the consolidated area about the abscess cavity broke down and ruptured in the direction of the least resistance, viz., toward the incision in the chest wall, was there any pus. That there was a damming back of pus is proved by the cessation of cough and expectoration for eight days after operation, and then suddenly the patient was nearly choked by a gush of intensely fetid pus upward, while at the same time pus flowed in quantity through the incision in the chest wall, and so continued to do, whereupon the cough ceased and also the expectoration, showing that gravity drainage was effectual. The patient, while much exhausted and run down, gained slowly and steadily and, having the best climatic conditions, recovered. Had he remained in the County Hospital among tuberculous patients he would have almost certainly succumbed to the disease.

The second case is as good a test of this mode of treatment, by reason of his less vigorous physique and long exposure to the sudden changes of Iowa and Nebraska and the greater progress of disease and the naturally depraved fiber of the man. If this patient, who is convalescent now, does not recover he will have demonstrated the correctness of the theory of this mode of treatment just as well as does Case 1. This man's septic symptoms stopped at once, his temperature fell, he did not cough, was more comfortable and gained weight slowly but steadily, leaving the hospital at the end of the eighth week. He is now under the care of my colleague, Dr. Shorb.

Both patients took the anesthetic—ether—badly and almost collapsed on the table. In each, owing to bad general conditions, the operation could not be completed as planned, and in each, owing to the handling and exploring with the finger as much as we dared, we accomplished indirectly what we otherwise would have done had the patient borne prolongation of the operation well. The fact that we did not do and find what we expected does not detract from the merits of the operation and the benefits to the patients, and we shall always feel that we did the correct thing and are ready to do the same operation again for similar conditions, only hoping it may not be necessary to hurry or change plans.

A half-completed operation is better than a dead patient, and the beneficial results from the half-finished and changed plan of operation are just as satisfactory to the patient if not to the operator. These patients knew exactly what they had to expect—discomfort, suffering and certain death under the usual let-alone or roundabout medicinal plan of treatment on the one hand, and a slim chance for betterment by the proposed operation on the other. The second patient was being examined in my office when the first came in, looking so robust and well that these men, the one recovered and the other considering the same plan of treatment, were introduced to each other and had many talks before the second consented to operation, and that he did so was only due to the proof of benefit exhibited to him by the other's recovery and his satisfaction with operative treatment.

I wish to acknowledge my indebtedness to Dr. J. de Bart Shorb, of Los Angeles, for his valuable suggestions and assistance in the treatment of these patients.

DISCUSSION.

Dr. John B. Murphy, Chicago—The purpose of drainage of the chest is a very important one, but I will not go into the objections attending it. The methods of drainage are two, internal and external. We can either drain the abscess through the bronchi or an external opening. We drain through the bronchi where we have no adhesions, but where we have adhesions the life of the patient would be jeopardized. If we make an incision into the chest cavity we immediately have the entrance of air. Through the opening you can grasp and palpate the abscess. Unless great care be used you are likely to have a septic pleurisy develop. You have an operation that can be performed with comparative safety, which is that of pressing the lung, allowing the pus to escape through the onchus. You can also puncture the chest and allow the patient to inspire air. About 170 cubic inches of air may be aspirated, and the patient can have his chest filled every third day if you wish to hasten the process. There is no inconvenience from air taken in that way. Of all the injections of air into the pleural cavity we have had but one accident, and that was where the needle was inserted while the tube was connected. I never have the tube connected when I wish to insert air into the chest. By this method you can fill air into the chest and drain the cavity effectually, but in cases of adhesions this is impossible. Many surgeons fear to open the chest, but their fears are groundless. You can palpate the lung just as well as you can palpate in the pelvis, and you can locate your abscess exactly. Do not make the mistake of endeavoring to reach it with a Paquelin cautery, for you will find the lung will retract in the chest out of reach of the cautery, unless an incision be made in the chest wall large enough to enable you to seize the lung or unless it be adherent. You will have less oozing in these cases than you might think for, but the abscess will heal perfectly.

Dr. Le Moyne Wills—Of course we have the advantage of a dry climate, which means a great deal in these cases; otherwise my patients would almost certainly have died. The second case was operated on only last January, while the other case was operated on two years ago.

The first case spent fifteen months, after leaving the Los Angeles County Hospital, in the San Jacinto Valley, in the open air, at light work, and was undoubtedly greatly assisted in his cure by climatic conditions. Had he remained in the County Hospital he would certainly have died. You do not have the opportunity to place your patients in such an atmosphere. These are not the kind of cases you see, whereas we see many of them.

I have experimented on rabbits from time to time since 1892, and have learned much from my work. My patients had the courage to consent to, and go through with, the operation and are perfectly satisfied with the result, although the surgeons may not be. The second case is not likely to live long, but is much more comfortable and will live longer than he otherwise would have done, without external drainage. The first man practically got well by over-flushing with a strong solution of mercury bichlorid, for I really believe the bichlorid did it. He is doing manual labor, keeps up his weight and strength, and is perfectly satisfied. I hope to be able to continue this subject at a later date.

SURGICAL ERRORS IN SKIAGRAPHY.*

CARL BECK, M.D.

NEW YORK CITY.

The ease with which some small bones of the human body can be reproduced by the Roentgen rays on a photographic plate led many medical novices, and even ignorant laymen, to the indiscriminate use, or rather abuse, of the rays.

For the ignorance of unskilful operators many distorted Roentgen ray pictures are responsible. Some of them caused such fatal errors that even well-experienced medical men felt a great disappointment in the results. But in considering all these errors, some of which were indiscriminately heralded through the medical as well as the lay press, it becomes evident that the Roentgen rays never lie, but that it is entirely our own imperfection which induces some of us to err under peculiar circumstances.

In the first place, we should never forget that a so-called Roentgen-ray picture is by no means an ordinary photograph of an object, but a silhouette only (skiagraph), i. e., a photograph of its shadow. To interpret such shadows properly a thorough knowledge of the normal anatomic relations of the tissues, especially of the bones, that produce such shadows, is required. As the most minute gradation of density is registered, the importance of being thoroughly acquainted with the anatomic relations of the bones producing the doubtful shadow is obvious, and for this purpose it is necessary to have the pictures of the shadows of the normal structures of the body always at hand for comparison.

There are slight irregularities of the surface of normal bone, which we could neither recognize nor appreciate before the Roentgen rays were discovered. Their shadows may at first sight appear to represent pathologic processes, but prove to be normal by thorough comparison with a normal skeleton. On certain portions of the normal skeleton the muscles and tendons would naturally cause obscure shadows. The carpus is especially likely to produce such errors in the skiagraph; the tuberosities of the trapezium, the scaphoid, the hamulus ossis hamati, the os pisiforme, and the eminentiæ carpi volaris radialis and ulnaris double up the thickness of the carpus, thereby causing dark shadows which might be mistaken for foreign bodies. Similar considerations and similar cautions apply to the other diagnostic opportunities offered by the rays.

If a skiagraph of the human hand is taken, for instance, the plate will show the least light where the bones rest, while the soft tissues appear opaque. There is also a difference of opacity according to the thickness of the tissues, their blood-supply, and their air capacity.

---

* Presented to the Section on Surgery and Anatomy, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

The foot, while easily skiagraphed in the direction of the dorsum toward the planta pedis, from the toes up to the upper third of the metatarsus presents an obstacle farther backward in the first and third cuneiform bones and the scaphoid, so that it is necessary also to skiagraph the foot on these portions transversely by having the outer surface rest on the support. It is by this procedure only that the isolated shadows of the astragalus, the calcaneum, the os cuboidum, the scaphoid, and the fourth and fifth metatarsal bones can be distinctly outlined, so that false interpretations may be excluded.

In the early era of the Roentgen rays the normal sesamoids were also sometimes incorrectly interpreted.

How important the knowledge of minute anatomic detail is, especially of non-pathologic abnormalities, will be evident from the fact that the os intermedium cruris —os trigonum tarsi—has been mistaken for a fragment severed from the astragalus. This bone is a typical part of the tarsus of all mammalia, and is estimated at from 7 to 8 per cent.

Shepherd, who mistook this bone for a fractured fragment, says: "The fact that this fracture is not mentioned in any of the text-books of surgery or in special treatises on fractures would easily be accounted for by its only being discovered by dissection; it causes no deformity, and the symptoms it would give rise to during life would probably be obscure." The same author tried to produce this fracture artificially on the cadaver, but "in every case," he says, "where this maneuver was performed, I failed, even when the greatest force was used, to break off the little process of bone mentioned above." Pfitzner regards the os trigonum tarsi as an integral part of the posterior process of the astragalus in the adult, which is analogous to the os intermedium antibrachii.

The practical significance of this bone is evident from a case described by Williams, which is also highly interesting from a medicolegal standpoint: A laborer claimed that he was injured by an iron bar, on Jan. 20, 1897, but was able to work during the whole day, but the following day he called on Dr. Wilmans, complaining of intense pain at his internal malleolus. He limped and emphasized his inability to work. Dr. Wilmans found a slight swelling below the right internal malleolus. Ecchymosis of the skin being absent, the swelling was attributed to the presence of a considerable degree of talipes, from which the laborer suffered at the same time. The leg was elevated and fomentations were applied for several days. The laborer still complaining of great pain, it was decided to transfer him to a hospital for observation. When discharged, after several weeks of treatment, he made an effort to resume work, but at once declared that he was unable to keep it up. He was therefore admitted to another hospital, where he repeated this maneuver several times during a period of six months. Finally he claimed damages for having been crippled by the injury sustained on the date above, but in view of the negative objective condition found by Dr. Wilmans, the society decided not to grant any claims. The consequence was that the laborer was transferred to the surgical division of a third hospital for further observation. There he complained that he had continuous pains below the right external malleolus, even while in the recumbent position. The pain increased while walking or sitting. Stepping on the right heel, he also declared to be impossible. By distracting his attention, however, it was noticed that he could stand well on his heel, and he would undoubtedly have been declared a malingerer had not the Roentgen rays, mirabile dictu, come to his rescue, at least temporarily, for a skiagraph showed a bone-fragment at the junction of the astragalus with the posterior surface of the calcaneum. On the strength of this skiagraphic "proof," Dr. Wilmans, although still mistrusting, was forced to modify his original opinion, and certified that the patient suffered from "fracture of the astragalus, in consequence of which he was damaged for life." The laborer therefore received an annuity of 30 per cent., in proportion to the estimated curtailing of his wages.

Soon afterward the laborer was discovered by Dr. Wilmans carrying a heavy load without any apparent pain, while formerly he had claimed to be unable to walk without a cane or a crutch. The Doctor insisted on a second irradiation, this time also skiagraphing the uninjured left foot. The skiagraph showed the "severed bone-fragment," which had first been regarded as a sesamoid of the musculus flexor longus hallucis, but which was now recognized as a normal os intermedium cruris. The society, of course, refused the annuity, and the German Supreme Assurance Court, to which the laborer had appealed, not only sustained the verdict of the society, but also decided that the laborer must return the annuity which he had unjustifiably enjoyed for eighteen months.

The significance of a skiagraph for the purpose of estimating the degree of functional disability is not always conclusive. A skiagraph may show a considerable degree of bony deformity after a fracture, and still the function may hardly be disturbed at all. Skiagraphic test has shown that, as a whole, even our best functional results show by no means an ideal union. An unscrupulous patient who secures possession of a skiagraph of his own case which shows considerable deformity, may, although there is no functional disturbance, strongly appeal to a jury on the strength of his skiagraph, if he succeeds in simulating great impairment. On the other hand, there may be but little evidence of bone-injury on the skiagraph, but there may be severe impairment of function on account of the injury to the soft tissues—circulatory, trophic or inflammatory disturbances—which can be represented only faintly, if at all. This shows the necessity of considering all the other clinical symptoms in connection with the skiagraph.

While it is easy, even for a layman, to understand the significance of most skiagraphs, there are, as alluded to, injuries the correct interpretation of which presupposes, besides thorough anatomic knowledge, the greatest care and a vast amount of experience as to the different modes of delineation in various projection-planes. The greatest diagnostic difficulties are offered by the joints. The more complicated a joint is the more complicated the skiagraphs of its various positions will naturally appear. It is especially the elbow-joint and hip-joint which are kept in view. First of all, the interpretation of the displacement caused by supracondylar fracture of the humerus and the deformities resulting from it later on, may tax the power of discrimination considerably.

The older the fracture, the less conspicuous the fracture-line will appear, since it will be more or less overshadowed by the callus. In old fractures the lines can not be represented as such, and it is only in case of union in a displaced position that its features could be guessed. In one of my cases, for instance, a second skiagraph was taken three years afterward, which showed essentially the same features as the first one, which had been taken four weeks after the injury.

In the case of the entire absence of displacement, only a very distinct skiagraph that shows the line clearly. It is natural that in such cases there is no skiagraphic evidence after recovery—that is, in from four to ten weeks, according to the type of the fracture.

If such a case fails to be skiagraphed shortly after the injury, no evidence of the fracture may be subsequently obtained. On the other hand, callus formation may be so abundant that, in spite of the absence of displacement, the fullest evidence of fracture may still be furnished months after. In one of my cases callus formation was so excessive that the attending physician was accused of malpractice, and it was the skiagraph only which convinced the patient that his physician had treated him correctly, the bones being in perfect apposition.

The intra-articular fracture types offer the greatest diagnostic difficulties, inasmuch as the fracture-line is also obscured by the callus formation. If, however, a skiagraph of the other joint is made at the same time, in the same position, and in the same projection, the various delineations of the shadows will be correctly understood and interpreted.

A normal skeleton should always be compared on the skiagraph. It should particularly be remembered that certain pathologic conditions—such as rachitis, for instance—influence the outlines of the bones and may deceptively be supposed to represent a portion of an injury. In such an event the skiagram of the fellow-extremity will set matters right.

In very young children the eminentia capitata appears as if entirely severed from the humerus, although the relations are absolutely normal. The explanation of this very important phenomenon is that the epiphyseal tissues are not sufficiently ossified to produce a shadow on the plate. If these points are not thoroughly considered, a displaced fracture-fragment might be erroneously diagnosticated.

Union between the epiphysis and the diaphysis of the head of the humerus is not perfect before the twentieth year. The lower epiphysis of the humerus consists of four nuclei, which do not ossify before from the eighth to the seventeenth year. The epiphyses of the trochelea, as well as of the olecranon, do not ossify before between the seventh and twelfth years, which explains why an osseous nucleus that is still connected with its neighboring epiphyseal nuclei, and the diaphysis by cartilaginous tissue, appears as an isolated piece of bone which might erroneously be taken for a fragment. The acromio-clavicular junction sometimes shows, in the skiagraph, a hiatus the width of a finger, so that a diastasis of the joint might be assumed. But since our knowledge on this new subject has increased, we know that this apparent diastasis is by no means pathologic, and that there is a normal gap between the osseous ends of the acromion and the acromial end of the clavicle. The upper epiphysis and the diaphysis of the radius unite between the seventeenth and the eighteenth year, and its lower epiphysis and the diaphysis join in the twentieth year. During the early Roentgen era the translucent space above the epiphyseal cartilage in children was erroneously taken for a fracture-line. The head of the femur unites with the diaphysis at the eighteenth or nineteenth year and the lower epiphysis follows after the twentieth year. The upper epiphysis of the tibia unites with the diaphysis in the twentieth or twenty-second year, while the lower tibial epiphysis unites with the diaphysis between the eighteenth and the nineteenth year.

For the thorough interpretation of skiagraphs in children, it is important to know that at birth the diaphyses of the radius, the ulna, the metacarpal bones and the phalanges are ossified, while their epiphyses, as well as the whole carpus, are still cartilaginous. It is not before the seventh year that an osseous nucleus shows at the lower epiphysis of the ulna. Union with the diaphysis sometimes begins with the twelfth year, but, as a rule, not before the fifteenth. Even then a small epiphyseal disc remains, which does not disappear before the seventeenth year in the female, and not before the nineteenth in the male.

The osseous nuclei of the carpus show at different periods, viz., at the os capitatum, at the fourth month; at the hamatum, at the fifth month; while the triquetrum shows its nucleus between the second and the third year, the lunatum between the third and fifth, the naviculare between the fifth and the seventh, the trapezium and trapezoid between the sixth and the seventh, and the os pisiforme between the eleventh and the fifteenth year. After five years the capitatum, hamatum and triquetrum have assumed their regular shapes, while the others, with the exception of the pisiforme, are perfectly developed at the twelfth year.

The osseous nuclei of the epiphyses of the metacarpal bones show at the second year, their synostosis with the diaphysis taking place between the twelfth and the seventeenth year in the females, and at the age of 19 in the male. The epiphyseal nuclei of the phalanges are ossified between the fourth and the fifth year, their synostosis with the diaphysis taking place at the same age as that of the metacarpal bones—from the twelfth to the seventeenth year in the female, and between the sixteenth and the nineteenth in the male.

Regarding the elbow-joint, it must be considered that an osseous nucleus appears at the medial side of the capitulum humeri between the second and third year, another one in the internal epicondyle at the fifth year, a third in the trochlea between the eleventh and the twelfth, and soon afterward a fourth in the external epicondyle. The nucleus of the internal epicondyle unites with the diaphysis between the sixteenth and the twentieth year, but the other three nuclei form a synostosis among themselves at the seventeenth year and then form the uniform osseous epiphysis, which completes its synostosis with the diaphysis at about the twentieth. In the capitulum radii an osseous nucleus appears between the fifth and seventh year, and in the olecranon between the sixth and the eighteenth, both uniting with the diaphysis between the twentieth and the twenty-fifth and between the sixteenth and the twentieth year.

Regarding the knee-joint, it must be considered that the lower femoral epiphysis contains an osseous nucleus at birth, while the nucleus in the tibial epiphysis shows shortly afterward. At the fourth year both these epiphyses have completed their development, but they do not unite with the diaphysis before the fifteenth year. The anatomic text-books say that union takes place between the seventeenth and the twenty-fourth year, but a skiagraphic experience points to an average period of only sixteen. The osseous epiphyseal nucleus of the fibula appears between the second and the fifth year, and unites with the diaphysis between the eighteenth and the twenty-fifth, but the skiagraph dates this period earlier, viz., the fifteenth year. The osseous nucleus in the tibial spine appears between the eighth and the tenth year; the epiphyseal line disappears between it and the diaphysis at the fifteenth.

As to the bones of the foot, it may be said that the lower epiphyses of the tibia and fibula show their osseous nuclei in the first and second years, and unite with the diaphysis between the eighteenth and twenty-fifth; according to skiagraphs, as early as before the eighteenth year. The osseous nucleus of the astragalus and calcaneum appears intra-utero, that of the cuboid shortly before or after birth, that of the cuneiform bones between the first and the fifth year, and that of the os naviculare from the first to the fifth. The osseous nuclei of the metatarsal bones and the phalanges appear from the second to the tenth year, and unite with the diaphyses between the sixteenth and the twenty-second.

In elbow-joint fractures occurring in childhood it is necessary, therefore, to take at least two skiagraphs in different projection-planes and to compare them thoroughly with the normal fellow. In a case of fracture of the femoral head, for instance, the deformity had appeared three times as large as it actually was, on account of inappropriate projection. The degree of shortening of the limb was accordingly overestimated. This shows the necessity of considering the other clinical symptoms and data in connection with the skiagraph.

In fractures of childhood it should also be remembered that the process of ossification is influenced by various affections of the bone, as, for instance, in rickets.

How important the question of projection is becomes evident when we consider that grave errors may sometimes occur even if all the preliminary conditions required for a thorough understanding of the case seem to be fulfilled. This will appear from the following experience, which has probably not been paralleled in the literature of this subject:

A boy 4 years of age, while playing in the street, fell against an iron bar. Being unable to rise again, he was taken up and carried to St. Mark's Hospital, where the first instance of moderate pain was noted, besides the functional disturbance. There was no difference in level nor any other deformity, nor any shortening, nor the typical equinus position. A photograph taken two days after the injury only showed a very moderate and uniform swelling of the leg. Abnormal mobility and crepitus in accordance could be produced only by very rough manipulations.

On the day following the injury two skiagraphs were made, one in the dorsal and the other in the lateral position. To my surprise, the one which had been skiagraphed by a direct irradiation, the center of the platinum disc of the tube being perpendicular to the anterior surface of the leg, did not show the slightest indication of fracture, while the one which represented the leg irradiated from the outer aspect of the tibia showed a marked fracture-line. The fracture presented the typical oblique type in the middle of the tibia, the fracture-line running from anteriorly to above posteriorly, the upper, tapering fragment overlapping the lower end. No sideward displacement having been present, it can be understood why the rays reaching the long axis of the tibia in a vertical direction did not show the fracture-line. A very slight change in position, where the inclination toward the fibular direction amounts to less than 1 millimeter, brought out the fracture distinctly. If I had, as is the custom in general, taken a skiagraph in the antero-posterior direction only, and if the manipulations made during the first examination had been carried out as gently as they properly should be, the fracture might have been overlooked entirely. And if, in view of the local pain and tenderness, the swelling and the functional disturbance, the possibility of a fracture had been seriously considered, the skiagraph might have silenced the uneasy conscience. This experience teaches the necessity of adopting the principle of always taking at least two skiagraphs in two different positions in all cases of suspected fracture.

In taking skiagraphs of foreign bodies it must be considered that their size varies according to the distance from the tube. In oblong bodies great errors as to their extent may be committed. Once I was very much surprised in a case where a needle-fragment had entered the palm of the hand in a perpendicular direction. The plate, while indicating the presence of the needle, distinctly created the impression that the fragment was only about 2 millimeters in length. When extracted it was found to be more than an inch long, the rays having reached the hand in a perpendicular direction so that the circumference of the fragment was reproduced rather than its length. A side view would have cleared up the error at once.

Misinterpretations have also arisen from unavoidable mechanical and chemical effects, causing markings in the photographic plate, the significance of which must be well known to the skiagraphic interpreter. Blemishes may also be produced by spots caused by pus from wounds or by perspiration. In the location of foreign bodies, especially in the skull, many errors were and are still committed. Their avoidance will be considered in a special article.

DISCUSSION ON PAPERS OF DRS. BECK, LEONARD AND DAVIS.*

DR. HOWARD KELLY, Baltimore—Dr. Leonard has presented a remarkable paper, and I feel sure he is doing the finest work of this kind. I have had a chance to test his skill in several cases of calculi. I had supposed until recently that in the female I had occupied this field pretty much for myself by making a diagnosis by slipping into the kidney my wax-tip bougie and finding the scratch marks on it when a stone is present; but recently I have had two cases in which I have been unable to detect the presence of the calculus in the kidney by this method, and in one of these cases Dr. Leonard cleared up the diagnosis. A patient came to me with a renal calculus on the left side, and on catheterizing the kidney I drew off a small amount of urine containing pus, but got no scratch marks. I then catheterized the other side simply to ascertain its condition, and there I unexpectedly got the scratch marks on the bougie. I therefore had a pyonephrosis on one side and calculus on the other. I passed the catheter a second time and got scratch marks again. Dr. Leonard happened to be in Baltimore at that time and took a skiagraph which located a calculus also in the side first tested. I operated first on the worst side and ten days ago on the other side. We must all learn to do this work as Dr. Leonard does it.

To facilitate end-to-end anastomosis of the ureter, I have invented what I call an anastomosis guide, which is shaped like a long thin cartridge with a long handle to use it. I slit the ureter above the division and slip in the guide and bring the ends together and suture them over the guide. The ureter can be anastomosed into the bladder in the same way. It is sometimes necessary to make a long anastomosis of the ureter into the bladder, as shown by some of my cases. I remember a patient in whom a carcinoma obstructed a ureter. I brought the ureter into the bladder by devising a plan which originated some years ago by simply freeing the bladder from its attachments and pulling it up until it reaches the ureter; the bladder was then retained in this extreme displacement by suturing it to the psoas muscle on level with the posterior border of the pelvis. By this means I have secured a perfectly satisfactory anastomosis.

DR. A. D. BEVAN, Chicago—I want to congratulate Dr. Leonard on the very fine work he has been doing. Some of the early work in finding renal calculi by means of the X-ray was done by Dr. McArthur and myself in Chicago. At that time the work was rather crude and the only stones found were those of large size. I am inclined to believe that some of the cases which had stone were not always demonstrated by the X-ray, but recently the technique has been very much improved. I regard it as of the greatest possible value in the diagnosis of stone in the kidney and recall a case where its value in this connection was well demonstrated. The patient was 30 years of age and had all the symptoms of a renal stone. The patient was sent to me by Dr. Billings, of Chicago. Dr. Crane, of Kalamazoo, who has been experimenting somewhat with the X-ray, took much interest in the case and examined it with his own apparatus. He presented three pictures which showed a stone three-fourths of an inch below the last rib and also a very small shadow one-third of an inch in length and not more than one-twelfth of an inch in width below this large stone. To the outer side was seen a kidney-shaped shadow about the size of a bean. At the time of the operation the kidney was pulled out and the vessels were controlled by pressure so that the posterior border of the kidney could be split. The large and small stones were easily found, but there was no evidence of the third stone. Very thorough examination was made, but was unsuccessful. I had the X-ray picture in the operating-room and I measured with my eye as nearly as I could where the third stone was supposed to be. I then took a hypodermic needle and very readily found the second size stone in the kidney itself, which shows the great value of the X-ray. You would be surprised at the small size of the smallest stone, and I am satisfied that this method is the most valuable for diagnostic purposes that we have at our disposal. Where it fails it is largely due to improper handling or wrong interpretation; when you hear a man say it is misleading, be sure that either he does not take good pictures or he does not know how to interpret them. We must learn something about the technique and how to interpret the result gained.

---

* Dr. Davis' paper on "Treatment of Injuries to the Ureters" appeared in last issue; Dr. Leonard's paper on "Diagnosis of Calculus Disease of Kidney, Ureters and Bladder by Roentgen Method" appeared elsewhere.

Dr. J. Wesley Bovee, Washington, D. C.—Until recently we had very little evidence of the value of the X-ray in the diagnosis of biliary and renal calculi and I am very glad to learn that the work can be done so satisfactorily at the present time.

I was very much pleased with the way Dr. Davis presented the subject of ureteral injuries, and I have no doubt that the best method of uniting a severed ureter is by uretero-ureteral anastomosis. The end-to-end method is done in nearly all cases transversely, and, in one of my own, obliquely. The experiments with this method on dogs has not been carried out on man in but the one case. The lateral anastomosis by Dr. Weller Van Hook is a good method, and recently another method of lateral anastomosis similar to the way it is performed in the intestines has been brought forward in Italy. The operation by different methods has been done 21 times on man, and an unfavorable result followed in but one case. Anastomosis with the bladder is a good operation and has been done something like 70 times. The point on which I do not agree is concerning the failure of the rectal or colon implantation, which has been done over 80 times and in a large number of cases has been successful. If we remember the work done by some of the foreign surgeons and get their statistics we shall find that they are successfully implanting the ureters into the bowel. The implantation of the severed ends of the ureter, however, has not been very satisfactory here, if we may judge from experiments on dogs, but the dangers have been greatly overdrawn. There has not been a case reported of marked stenosis in uretero-ureteral anastomosis, except one where tuberculosis was present; this may have had something to do with it, and the operation was not necessarily faulty.

Dr. George Goodhue, Dayton, Ohio—It was my experience six years ago to have a patient who complained of pain over one side in the kidney region, but not on the other. A surgeon of large experience was called in to operate on this man, and removed the kidney from the side which gave him the trouble, although it was very slightly, if at all, diseased. The other kidney I removed at the autopsy several months later, and found it packed with stone. I simply mention this to show what the X-ray might have done had we had it at that time. Only an hour or two before I left home I had a patient, who gave every symptom of renal calculus, subjected to the X-ray, but I came away too soon to learn the results. I would like to ask Dr. Leonard to state what part of the surface should be exposed to get the best results, i. e., whether the posterior, anterior or lateral. Our work is being done by a man who is doing excellently in this line. Later I shall report a case of successful anastomosis of ureter by implanting the upper section into the lower through an opening made into the side, as recommended by Kelly.

Dr. Randolph Winslow, Baltimore—Four years ago, while doing a hysterectomy, I was unfortunate enough to cut a ureter. I was aware of the work that had been done by Van Hook and Kelly, and I made an incision into the ureter, slit it up, invaginated the upper end into the lower, closed the lower end over the upper, and the woman recovered. The operation, so far as I can see, does not differ from the one the reader of the paper has presented, except that I used silk instead of catgut. The woman has remained well for three years, and I believe is still so. All of these operations are merely modifications of the original method of Van Hook, and to him is due the credit for whatever success has been accomplished. The ureter is ordinarily described as terminating in the pelvis of the kidney, which, passing through the sinus of the kidney, forms a large dilatation within the substance of this organ. This description is not correct in most cases. The pelvis of the kidney is usually quite a small structure and may be either fusiform or triangular, or more or less quadrilateral in shape. From the pelvis issues several long and narrow tubes, usually at least four in number, which terminate in calices after passing a considerable distance, perhaps an inch or more in length. You may have a stone in one of these calices. You may pass a ureteral catheter, which will go into the pelvis or into one of the calices, but not in the one where the stone is impacted. A stone developed in the lower calices can not be reached in this manner.

Dr. Carl Beck, New York City—It seems to me to be a deplorable fact that the great importance of the X-ray has not been realized by the profession, and I only wish that more such beautiful and convincing explanations could be brought forward. I agree with every point but one, and that is that the skiagraph will always show whether a renal calculus is present or not. I think this is a dangerous statement. Although a man's technique may be splendid, yet he may commit some errors. I would not make a diagnosis on a negative skiagraphic report regarding the presence of renal calculi. While a positive skiagraph is proof enough for the surgeon, a negative skiagraph will not convince me there is not a stone. In a doubtful case at least two short and long exposures should be made, and if possible, with different tubes. It has occurred to me that renal calculi, if they be elliptical in shape, may be confounded with biliary calculi, particularly if the body is irradiated in the oblique direction, so that the calculus appears near the spinal column.

Dr. L. L. McArthur, Chicago—I agree with the last speaker, Dr. Beck, that not all calculi may be expected to be found with the skiagraph. I believe Dr. Leonard, in his paper, failed to emphasize sufficiently the fact that the chemical composition of the calculus determines the intensity of the shadow. A uric-acid calculus will give a very slight shadow. I made some investigations before attempting to photograph a stone in the kidney, and on taking a group of calculi of varying types I found that a pure uric-acid calculus gave a very feeble shadow. Since that time I have cut down and found uric-acid calculi which were not demonstrable by the X-ray in the hands of our expert in its use, Mr. Fuchs.

Dr. J. E. Summers, Jr., Omaha—Dr. Davis' technique is practically identical with that adopted years ago by Joseph Price, and is, I believe, as simple as any, being particularly advantageous when there has been a loss of substance and under such circumstances has an advantage over Van Hook's method. One must remember when operating on the ureter that it may have a fellow on the same side and that these ureters may come from a horse-shoe (more or less fused) kidney. Those who have examined the pathological exhibit will remember a specimen of double ureter on both sides, there being two separate kidneys. Recently I did a left-sided nephrectomy for tuberculosis; the patient was a female, aged 2½ years. There were two ureters on this side and a large kidney. Fearing the possibility of a single kidney, I button-holed the other side in order to examine for the presence and condition of the right kidney. The kidney was removed together with the ureters, the lower one, which was healthy, was removed only in part, the upper, which was tubercular, was removed to below the pelvic brain. The child recovered nicely.

Dr. F. B. Carpenter, San Francisco—Seeing Dr. Kelly requested that all cases like his own should be reported, I will report one to add to the list. I brought the upper end of the ureter down to meet the lower, and consequently tied off the lower, destroying the mucosa that remained. I then made a large incision in the posterior wall of the bladder and passed three catgut sutures from within out to the upper end of the ureter. I brought the ureter firmly down from the lower angle of the incision into the bladder. When this was once secured I closed the remaining portion of the long incision into the bladder, and the patient made a good recovery, without any bad symptoms. I would call attention to an idea I derived at the time of the operation. It occurred to me that hereafter I could make use of Murphy's idea of a button in making anastomoses between the lower end of the ureter and the bladder. One important thing in this connection was that when the button came away it must necessarily fall into the bladder and could then be brought out through the urethra. The button will probably be slow, as our experience with buttons passing into the intestine has been. Phosphatic deposits may accumulate, which will cause some delay.

Dr. C. L. Leonard—I purposely refrain from speaking of the technique of skiagraphy, as I have just published a full description in the *Annals of Surgery*, and reported 59 cases in which I had found 12 calculi. Of those calculi a chemical analysis has been made, which shows that they consist of all the varieties except cholesterin. Uric-acid crystals, carbonates and phosphates are all represented. The reason why these calculi may now be detected by the X-ray, but could not at first, is due to the different quality of the X-ray I use. If you use a tube that has an equivalent resistance of 2 inches you will penetrate a uric-acid stone, but if, on the other hand, you use a tube which has a resistance of 1½ inches and will stay at that point, you will not penetrate the uric-acid stones. I found a calculus that weighed nine-tenths of a grain, while another of pure uric acid was removed from the ureter and weighed two and three-quarter grains. I had hoped to be able to show you some slides demonstrating these calculi. One of those slides shows 7 calculi that have been taken with different qualities of the X-ray, but with all other conditions equal. It shows that vacuum tubes will penetrate uric-acid stones, while the low vacuum gives opaque shadows, and it is this improvement in the technique that has made it possible for me to develop the method which I now use and which is so essential. I use a light which will not penetrate the less opaque calculi. If you get in the negative a shadow of the lumbar muscles you may be absolutely sure that no calculi exist. The only case of error in either positive or negative diagnosis was made in a case examined for Dr. W. W. Keen. It was an error in technique and served to show that the method *per se* was not at fault. The plate had not been placed sufficiently high, so that a calculus in the upper pole of the left kidney escaped detection. This error only served to strengthen my belief in the correctness of the method and helped to improve my technique. A second case for Dr. Keen showed that I was amply justified in my faith in the method, even to the extent of opposing his diagnosis. The symptoms were sufficiently severe to justify operative intervention, but the result of the operation coincided with the negative diagnosis. It is the method which I believe is absolute, the errors are entirely the result of faulty technique in applying it.

Dr. B. B. Davis—I have certainly succeeded in getting some more cases reported, if my paper has accomplished nothing else, and this will make these cases of record. In practically all instances where there has been a ureter severed at the time of operation the patient is exhausted and the surgeon is tired before the operation is completed, and consequently we want to have a method of repair which will be as simple as possible. The quicker it can be done the better will it be for all concerned. Kelly will do his operation very quickly, of course, but for the average operator I think it will take a good deal longer time than the method I have described. Although I do not profess to be a rapid operator, I am sure it did not take me more than five minutes to finish up the anastomosis. Catgut soon dissolves, so that there is no danger from the suture. As to the button which has been shown, I can not but think that with such a small lumen as it must necessarily have, it is almost sure to be filled by the phosphates before it separates.

WALLED OFF.*

JOHN B. DEAVER, M.D.
PHILADELPHIA.

"Walled off" is an expression so often heard in connection with cases of appendicitis which have gone on to pus formation, that I have selected it for the subject of dicsussion. When I hear a physician boast that his case has advanced to this stage and is ripe for operation, I often wonder how it is possible for him to have been unaware of the dangers to which the patient has been subjected and feel sorry for the physician's or surgeon's lack of knowledge of the living pathology of this vicious and deceptive disease that he has allowed to stealthily advance to that point where he believes he has every reason to congratulate himself. The most charitable view one can come to is, that he is familiar with operation under this one circumstance only.

In order to make clear the object of this paper, let me draw the comparison between an operation for walled-off pus, and operation in the absence of pus, or before the pus has become walled off.

Before taking up the arguments in favor of early operation and against late interference, let me impress on you that the mere evacuation of an appendicular abscess, drainage and subsequent healing of the abscess does not insure the patient immunity from a subsequent attack of appendicitis. A recurrent attack is much more likely to follow a partial operation—where the appendix is not removed—on account of the retention of an appendix which is damaged, therefore more vulnerable, and a fruitful source for subsequent attacks. That the appendix, in the case of a walled-off abscess, is frequently discharged as a slough, I am prepared to deny. The surgeon or the physician deceives himself, the patient, and the patient's friends when he makes this statement. I have repeatedly operated on cases in which a walled-off abscess had been drained, and in not one have I failed to find the appendix. At this time I may say that I have never met with a case where the appendix was normally absent.

Walling off of an abscess is nature's means of protecting the general peritoneal cavity. It has been stated that nature should be allowed to pursue its course unhampered by human skill or interference. The fact must not to be lost sight of, that nature in dealing with pathological conditions does not work with the same immutability that it does with other normal laws, and therefore there is always to be considered the probability that the lauded and longed-for walled-off condition may fail to materialize, thus leaving the patient far worse off in the second state than he was in the first. The fact that a sufficient number of cases which constitute a large series is warrant enough for a decided opinion enables me to say without reservation or fear of successful contradiction few cases of abscess are completely walled off.

---

* Read before the Profession of Springfield, Mass., at the Mercy Hospital.

What is to be gained by waiting until the abscess is walled off? Shall we allow the unfortunate patient to perish, or have one or more of the many serious complications that go hand in hand with abscess in the peri*toneum?*

To recover from an operation for a walled-off appendicular abscess, means, to say nothing of the many risks to life, an indefinite convalescence. Abscess formation in appendicitis is a preventable complication and certainly a desirable one to eliminate from the treatment of the disease. I fully realize the difficulty experienced by physicians in some instances to convince the patient and their friends that early operation is the course of wisdom. This is the exception and not the rule, as the laity more often raise the question of operation when they are told that the case is one of appendicitis.

What can we expect when many of our prominent surgeons are still crying down too-early operation. Against the latter dictum, just criticism is in order. It is my experience and yours as well, I am sure, that the surgeon and physician who has had the largest experience with this disease and particularly those who have studied the living pathology, that is having seen in the living belly-cavity this vicious inflammation when in full force, are those who advocate, yes, pray for early interference.

When I hear the surgeon or physician say, "let us wait twenty-four hours longer," I am sure their experience has been limited and therefore they are not qualified to give an authoritative opinion on this important question. Many lives have been sacrificed by procrastination, while I dare say not one, except through faulty technique, perhaps, has been lost by too-early interference. Great is the number of surgeons and physicians who have regretted operating too late in appendicitis, while I venture to declare that if this country were raked with a fine-toothed comb not one could be found who regrets having operated too early. This is the doctrine to inculcate into the minds of our medical friends if we would reduce the mortality of this disease and do away with complications and sequelæ.

It has been said that not to be able to discriminate between cases of appendicitis which require immediate operation and those in which operation can be deferred for one or two days, or until the attack has subsided, is unscientific. In answer to this I beg to say that this kind of science which is killing many human beings daily should be thrown to the dogs. I challenge any one to interpret to a certainty the pathological condition in a case of an acute inflammation of the appendix, unless the opportunity is given to see inside the belly-cavity. To be plain, this sort of pretention is disgusting to say the least. I tell the students attending the clinic at the German Hospital that I know but two things in a case of appendicitis, namely, that the disease is an inflammation of the appendix and that the appendix should come out.

To foretell the extent of the diseased condition on the inside of the abdomen by an external examination I am unable to do. Perhaps my colleagues who have seen only little of this class of operations can, and if so, they are wiser than I am.

Statements such as the following, that "I have had two hundred cases of appendicitis and never lost a patient, nor have I had to have one operated on," is false beyond question. Many of the gentlemen who have never lost a patient have waited until the eleventh hour and then sent for the surgeon, who very foolishly operates, is credited with the death, and relieves the attending physician of counting this against his record.

There are five forms in which appendicular abscess are met with, depending on the locality in which the collection is situated. I will discuss them one at a time and try to convince you of the futility of depending on nature to control intraperitoneal suppuration and its effects, by the process of walling off.

1. The most common in my experience is when the collection is post-cecal, or post-colic, and between the layers of the mesocolon, it is a walled-off collection, but not walled off so as to avoid infection of the peritoneum in its evacuation. The parietal peritoneum does not enter as a part of the abscess wall, and therefore in opening the abdomen to get at the collection the general peritoneal cavity must necessarily be opened and unless gauze be properly distributed so as to make up for nature's deficiency the general peritoneal cavity will be endangered. It may sometimes be possible to open the collection through the loin space, but this means an element of uncertainty as well as simply evacuation, leaving the appendix. I think it is inadvisable, and to a degree dangerous. If any class of surgery should be complete it is appendicular surgery.

2. The second variety of walled-off pus is where the collection is found directly beneath the parietal peritoneum and its limiting wall is formed by the cecum, coils of small intestines, the omentum, the appendix, the parietal peritoneum and masses of lymph binding these together. This is the variety of walled abscess which the advocates of the "let alone" theory hope to secure by their masterly inactivity. This variety occurs second in order of frequency of the walled-off type of appendicitis. In this class of cases it is a most common occurrence to find that the abscess is in communication with, and includes, the pelvis. To complete the operation in this type we must protect the peritoneal cavity from infection with protecting gauze, evacuate the collection, remove the appendix, introduce drainage, both tubular and gauze.

3. In the third variety of walled-off abscess, the collection is wholly confined to the pelvis and shut off from the general peritoneal cavity. The pus can not be evacuated without endangering the peritoneal cavity unless gauze packing is extensively used to protect it. The appendix will always be found to be located in the pelvis and therefore its removal must be accomplished before completing the operation.

The evacuation of a pelvic collection of pus, the result of an appendicular inflammation, by vaginal or rectal puncture is to be heartily condemned for several reasons; that it is contrary to sound surgical principles; that it is attended by certain risks; that it does not remove the source of disease; and, that it is at least only a very dangerous and temporary makeshift. By attacking the pelvic collection of pus through the abdominal wall, the appendix can be removed and the pus cavity properly treated, thus favoring healing by the process of granulation.

4. The fourth variety of walled-off pus is found located near the median line of the abdomen and to the inner side of the cecum. The retaining wall is composed of cecum, appendix, small intestine, mesentery, omentum, and possibly the sigmoid flexure of the colon. In order to operate with more safety to the patient in this variety of abscess it may be necessary to make a second incision to the median side of the incision which opens the pus cavity, so as to protect the peritoneum with

gauze packing in order to complete the operation by removing the appendix.

5. The fifth variety of appendicular pus is found free in the peritoneal cavity. In this variety there has been no attempt on the part of nature to confine the pus. This, the most unfortunate variety, especially if the patient is not operated on within the first twelve hours, in that the patient's chances are reduced almost to nil. The attempt to treat this variety of abscess sucessfully will depend on the thoroughness of the technicpue, which will sometimes secure a favorable outcome to the case.

The writer's successful cases in this variety of abscess have been where he has operated within the first six or twelve hours of the disease. The following case demonstrates the correctness of my position in appendicular surgery. I am very sure that had the operation been deferred in the case I report until the serofibrinous exudate had become pus, or until the appendix had perforated, this young physician's life would have been lost.

Patient was an interne of the German Hospital, operated on for acute appendicitis Oct. 1, 1900. History of previous attack was negative, with the exception of possibly an attack of the mildest character two years ago. On the evening of Sept. 30, 1900, after an especially hearty dinner, the patient had a little abdominal pain, which was general and cramp-like, but not severe. He took a dose of salts. The general pain complained of at first became better after salts had operated, but patient was left with some pain, which was referred to the right iliac fossa. The following morning, Oct. 1, the Doctor was on duty attending to his daily duties. About 12 a.m., Oct. 1, pain became so much worse that the Doctor went to bed. I saw him at 1 p.m., Oct. 1, when the diagnosis of acute appendicitis had been made by my house surgeons, Drs. Curry and Moore. I confirmed the diagnosis and operated immediately, finding the abdominal cavity filled with serofibrinous exudate, and appendix distended with pus. Recovery was uninterrupted; in fact, it was unusually smooth. Operation was made through a 1½-inch incision through the right rectus muscle.

Thus far we have dealt with cases which have advanced to pus formation. I shall now take up pus in the peritoneal cavity, whether free or confined, and endeavor to prove to you that it is far better to anticipate pus than to have to combat it.

Let us sum up the evidence of the possible results of appendicular pus, and in order to deal with it properly, divide it into two headings, general sepsis and local sepsis. Under the first, general sepsis, we must include septicemia, pyemia, pyelophlebitis, hepatitis, abscess of the liver, septic pneumonia, septic nephritis, etc. Under the latter heading we find adhesions, softened and gangrenous bowel and omentum, perforation of the bowel, bladder or ureter, fecal fistula, prolonged convalescence, ventral hernia, and subsequent obstruction of the bowel, either from bands or from the contraction of the abscess wall.

In drawing comparisons between the mortality in the presence of pus and operation done prior to pus formation, we know that operation in the presence of pus gives a percentage of 10 to 18 deaths per 100, while in the presuppurative stage the mortality is .5 per cent. This statement should make further argument unnecessary.

It is likewise proper that we consider the length of time necessary to establish convalescence under the two conditions. The recovery in cases operated on in the presence of pus is always problematical and the convalescence protracted, lasting anywhere from four to six weeks in the most favorable cases and in many instances to as many months, while recovery in those cases where pus is absent takes but ten to twelve days.

In considering some of the results of pus formation from appendicitis, fecal fistula is one of the most unfortunate. The most common cause for fecal fistula is pressure necrosis, due either to an extensive purulent collection, or from the very high grade of infection. By very early operation a fistula bue to either of these causes can be prevented. One of the common causes for a simple fistula is an unhealed abscess cavity. It is unnecessary for me to add that a fecal fistula too often is a most distressing sequel to appendicitis and difficult at times to cure, even with operative interference.

It has been my experience that walled-off abscess is followed by ventral hernia, the operation for the relief of which is attended by greater risk than is the original operation, and too often with less certainty of a permanently good result. Chronic sepsis is the natural result of a peritoneal abscess; this of itself is attended by a mortality.

There is no choice as to the time of operation in appendicitis; theoretically, there may be arguments advanced to refute this statement, but it is the results which impress us and from which we must draw the rules of guidance in matters which involve life and death. It has been claimed that appendicular pus becomes less virulent the longer it remains in the peritoneal cavity, and that in time it will become sterile but what of the poor unfortunate patient while this intraperitoneal sterilization of the pus is taking place?

It has been said that man can become accustomed to anything, even hanging, and it seems, if we accept the above claim, that he can even become used to having a collection of pus in his peritoneum until it becomes sterile, but that delay on the part of the patient, or by the consent of the physician, is good and sound treatment, I deny with all the strength I possess.

Let me insist that you have your cases of appendicitis operated on, yes, immediately after the onset of the initial pain. Do not be influenced by the pernicious doctrine that you can wait for further developments, as the latter teaching is at the cost of many precious human lives.

When I hear and read remarks like this, when in cases of appendicitis the symptoms are progressing unfavorably after twenty-four hours have elapsed, operate and operate immediately. I have unquestionable evidence of one of the reasons at least why the mortality in this disease is so high. Why should delay for twenty-four hours in the presence of unfavorable symptoms be entertained? My answer would be want of confidence on the part of one so advising.

It has been said, and well said, that he who stops to deliberate is lost; this is apropos of this discussion, for the physician or surgeon who stops to deliberate, that is, waits twenty-four hours, to operate in the presence of unfavorable symptoms, is not only lost in the sense that he is lost as to the knowledge of the living pathology of the disease, but that many more patients will be lost if this dangerous teaching is practiced.

In concluding my remarks on this subject I shall in brief review the salient points with especial reference to impressing them on your thoughts and ask your unbiased discussion in reviewing the facts:

1. Pus is an avoidable complication in the treatment of appendicitis.
2. The patient's welfare is best preserved by avoiding any of the complications incident to pus formation.

say without reservation or fear of successful contradiction few cases of abscess are completely walled off.

What is to be gained by waiting until the abscess is walled off? Shall we allow the unfortunate patient to perish, or have one or more of the many serious complications that go hand in hand with abscess in the peritoneum?

To recover from an operation for a walled-off appendicular abscess, means, to say nothing of the many risks to life, an indefinite convalescence. Abscess formation in appendicitis is a preventable complication and certainly a desirable one to eliminate from the treatment of the disease. I fully realize the difficulty experienced by physicians in some instances to convince the patient and their friends that early operation is the course of wisdom. This is the exception and not the rule, as the laity more often raise the question of operation when they are told that the case is one of appendicitis.

What can we expect when many of our prominent surgeons are still crying down too-early operation. Against the latter dictum, just criticism is in order. It is my experience and yours as well, I am sure, that the surgeon and physician who has had the largest experience with this disease and particularly those who have studied the living pathology, that is having seen in the living belly-cavity this vicious inflammation when in full force, are those who advocate, yes, pray for early interference.

Many lives have been sacrificed by procrastination, while I dare say not one, except through faulty technique, perhaps, has been lost by too-early interference. Great is the number of surgeons and physicians who have regretted operating too late in appendicitis, while I venture to declare that if this country were raked with a fine-toothed comb not one could be found who regrets having operated too early. This is the doctrine to inculcate into the minds of our medical friends if we would reduce the mortality of this disease and do away with complications and sequelæ.

It has been said that not to be able to discriminate between cases of appendicitis which require immediate operation and those in which operation can be deferred for one or two days, or until the attack has subsided, is unscientific. In answer to this I beg to say that this kind of science which is killing many human beings daily should be thrown to the dogs. I challenge any one to interpret to a certainty the pathological condition in a case of an acute inflammation of the appendix, unless the opportunity is given to see inside the belly-cavity. To be plain, this sort of pretention is disgusting to say the least. I tell the students attending the clinic at the German Hospital that I know but two things in a case of appendicitis, namely, that the disease is an inflammation of the appendix and that the appendix should come out.

To foretell the extent of the diseased condition on the inside of the abdomen by an external examination I am unable to do. Perhaps my colleagues who have seen only little of this class of operations can, and if so, they are wiser than I am.

Statements such as the following, that "I have had two hundred cases of appendicitis and never lost a patient, nor have I had to have one operated on," is false beyond question. Many of the gentlemen who have never lost a patient have waited until the eleventh hour and then sent for the surgeon, who very foolishly operates, is credited with the death, and relieves the attending physician of counting this against his record.

There are five forms in which appendicular abscess are met with, depending on the locality in which the collection is situated. I will discuss them one at a time and try to convince you of the futility of depending on nature to control intraperitoneal suppuration and its effects, by the process of walling off.

1. The most common in my experience is when the collection is post-cecal, or post-colic, and between the layers of the mesocolon, it is a walled-off collection, but not walled off so as to avoid infection of the peritoneum in its evacuation. The parietal peritoneum does not enter as a part of the abscess wall, and therefore in opening the abdomen to get at the collection the general peritoneal cavity must necessarily be opened and unless gauze be properly distributed so as to make up for nature's deficiency the general peritoneal cavity will be endangered. It may sometimes be possible to open the collection through the loin space, but this means an element of uncertainty as well as simply evacuation, leaving the appendix. I think it is inadvisable, and to a degree dangerous. If any class of surgery should be complete it is appendicular surgery.

2. The second variety of walled-off pus is where the collection is found directly beneath the parietal peritoneum and its limiting wall is formed by the cecum, coils of small intestines, the omentum, the appendix, the parietal peritoneum and masses of lymph binding these together. This is the variety of walled abscess which the advocates of the "let alone" theory hope to secure by their masterly inactivity. This variety occurs second in order of frequency of the walled-off type of appendicitis. In this class of cases it is a most common occurrence to find that the abscess is in communication with, and includes, the pelvis. To complete the operation in this type we must protect the peritoneal cavity from infection with protecting gauze, evacuate the collection, remove the appendix, introduce drainage, both tubular and gauze.

3. In the third variety of walled-off abscess, the collection is wholly confined to the pelvis and shut off from the general peritoneal cavity. The pus can not be evacuated without endangering the peritoneal cavity unless gauze packing is extensively used to protect it. The appendix will always be found to be located in the pelvis and therefore its removal must be accomplished before completing the operation.

The evacuation of a pelvic collection of pus, the result of an appendicular inflammation, by vaginal or rectal puncture is to be heartily condemned for several reasons; that it is contrary to sound surgical principles; that it is attended by certain risks; that it does not remove the source of disease; and, that it is at least only a very dangerous and temporary makeshift. By attacking the pelvic collection of pus through the abdominal wall, the appendix can be removed and the pus cavity properly treated, thus favoring healing by the process of granulation.

4. The fourth variety of walled-off pus is found located near the median line of the abdomen and to the inner side of the cecum. The retaining wall is composed of cecum, appendix, small intestine, mesentery, omentum, and possibly the sigmoid flexure of the colon. In order to operate with more safety to the patient in this variety of abscess it may be necessary to make a second incision to the median side of the incision which opens the pus cavity, so as to protect the peritoneum with

gauze packing in order to complete the operation by removing the appendix.

5. The fifth variety of appendicular pus is found free in the peritoneal cavity. In this variety there has been no attempt on the part of nature to confine the pus. This, the most unfortunate variety, especially if the patient is not operated on within the first twelve hours, in that the patient's chances are reduced almost to nil. The attempt to treat this variety of abscess sucessfully will depend on the thoroughness of the technicpue, which will sometimes secure a favorable outcome to the case.

The writer's successful cases in this variety of abscess have been where he has operated within the first six or twelve hours of the disease. The following case demonstrates the correctness of my position in appendicular surgery. I am very sure that had the operation been deferred in the case I report until the serofibrinous exudate had become pus, or until the appendix had perforated, this young physician's life would have been lost.

Patient was an interne of the German Hospital, operated on for acute appendicitis Oct. 1, 1900. History of previous attack was negative, with the exception of possibly an attack of the mildest character two years ago. On the evening of Sept. 30, 1900, after an especially hearty dinner, the patient had a little abdominal pain, which was general and cramp-like, but not severe. He took a dose of salts. The general pain complained of at first became better after salts had operated, but patient was left with some pain, which was referred to the right iliac fossa. The following morning, Oct. 1, the Doctor was on duty attending to his daily duties. About 12 a.m., Oct. 1, pain became so much worse that the Doctor went to bed. I saw him at 1 p.m., Oct. 1, when the diagnosis of acute appendicitis had been made by my house surgeons, Drs. Curry and Moore. I confirmed the diagnosis and operated immediately, finding the abdominal cavity filled with serofibrinous exudate, and appendix distended with pus. Recovery was uninterrupted; in fact, it was unusually smooth. Operation was made through a 1½-inch incision through the right rectus muscle.

Thus far we have dealt with cases which have advanced to pus formation. I shall now take up pus in the peritoneal cavity, whether free or confined, and endeavor to prove to you that it is far better to anticipate pus than to have to combat it.

Let us sum up the evidence of the possible results of appendicular pus, and in order to deal with it properly, divide it into two headings, general sepsis and local sepsis. Under the first, general sepsis, we must include septicemia, pyemia, pyelophlebitis, hepatitis, abscess of the liver, septic pneumonia, septic nephritis, etc. Under the latter heading we find adhesions, softened and gangrenous bowel and omentum, perforation of the bowel, bladder or ureter, fecal fistula, prolonged convalescence, ventral hernia, and subsequent obstruction of the bowel, either from bands or from the contraction of the abscess wall.

In drawing comparisons between the mortality in the presence of pus and operation done prior to pus formation, we know that operation in the presence of pus gives a percentage of 10 to 18 deaths per 100, while in the presuppurative stage the mortality is .5 per cent. This statement should make further argument unnecessary.

It is likewise proper that we consider the length of time necessary to establish convalescence under the two conditions. The recovery in cases operated on in the presence of pus is always problematical and the convalescence protracted, lasting anywhere from four to six weeks in the most favorable cases and in many instances to as many months, while recovery in those cases where pus is absent takes but ten to twelve days.

In considering some of the results of pus formation from appendicitis, fecal fistula is one of the most unfortunate. The most common cause for fecal fistula is pressure necrosis, due either to an extensive purulent collection, or from the very high grade of infection. By very early operation a fistula bue to either of these causes can be prevented. One of the common causes for a simple fistula is an unhealed abscess cavity. It is unnecessary for me to add that a fecal fistula too often is a most distressing sequel to appendicitis and difficult at times to cure, even with operative interference.

It has been my experience that walled-off abscess is followed by ventral hernia, the operation for the relief of which is attended by greater risk than is the original operation, and too often with less certainty of a permanently good result. Chronic sepsis is the natural result of a peritoneal abscess; this of itself is attended by a mortality.

There is no choice as to the time of operation in appendicitis; theoretically, there may be arguments advanced to refute this statement, but it is the results which impress us and from which we must draw the rules of guidance in matters which involve life and death. It has been claimed that appendicular pus becomes less virulent the longer it remains in the peritoneal cavity, and that in time it will become sterile but what of the poor unfortunate patient while this intraperitoneal sterilization of the pus is taking place?

It has been said that man can become accustomed to anything, even hanging, and it seems, if we accept the above claim, that he can even become used to having a collection of pus in his peritoneum until it becomes sterile, but that delay on the part of the patient, or by the consent of the physician, is good and sound treatment, I deny with all the strength I possess.

Let me insist that you have your cases of appendicitis operated on, yes, immediately after the onset of the initial pain. Do not be influenced by the pernicious doctrine that you can wait for further developments, as the latter teaching is at the cost of many precious human lives.

When I hear and read remarks like this, when in cases of appendicitis the symptoms are progressing unfavorably after twenty-four hours have elapsed, operate and operate immediately. I have unquestionable evidence of one of the reasons at least why the mortality in this disease is so high. Why should delay for twenty-four hours in the presence of unfavorable symptoms be entertained? My answer would be want of confidence on the part of one so advising.

It has been said, and well said, that he who stops to deliberate is lost; this is apropos of this discussion, for the physician or surgeon who stops to deliberate, that is, waits twenty-four hours, to operate in the presence of unfavorable symptoms, is not only lost in the sense that he is lost as to the knowledge of the living pathology of the disease, but that many more patients will be lost if this dangerous teaching is practiced.

In concluding my remarks on this subject I shall in brief review the salient points with especial reference to impressi[illegible]em on your thoughts and ask your un- [illegible]: in reviewing the facts:

1. Pus is an avoidable complication in the treatment of appendicitis.

2. The patient's welfare is best preserved by avoiding any of the complications incident to pus formation.

3. The walled-off abscess is not the blessing to be sought, but rather an evil to be avoided by prompt surgical interference as soon as the symptoms of appendicitis manifest themselves.
4. Operation on cases of walled-off pus imperils the patient's chances for recovery, on account of liability to infection of the peritoneal cavity.
5. Fecal fistula as a result of a walled-off appendicular abscess is an unavoidable sequel to appendicitis and should not be permitted to occur.
6. The latter statement is true of all complications and sequelæ of appendicitis due to pus formation.

THE ARMY SURGEON IN THE PHILIPPINES.

WILLIAM J. LYSTER, M.D.
ACTING ASSISTANT-SURGEON, U. S. A.
MANILA, P. I.

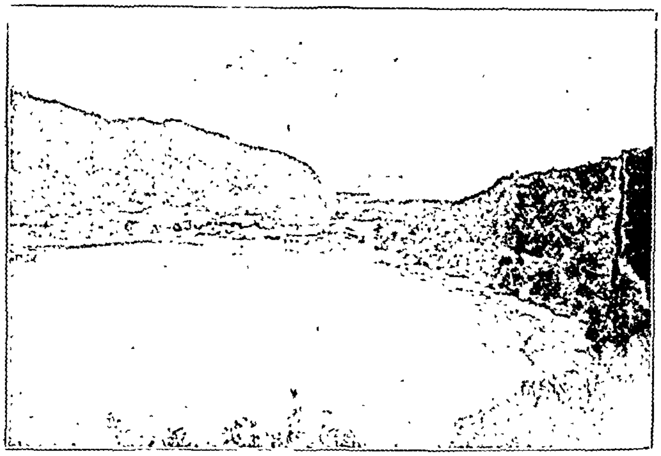
In a number of islands, stretched out through a thousand miles of the greatest of oceans, is the United States Army of occupation in the Philippines, holding positions in the interior of islands as large as the State of Ohio, many of whose inhabitants had never before seen the faces of white men. With the troops combating diseases of new type, among barbarous communities ignorant of all sanitary precautions, is the army surgeon, attempting to carry with him the principles and appliances of modern science necessary to the preservation of life, in a climate that is strange to him and which impels a study of its peculiarities at the same time that it increases his work. The medicines, instruments and foods necessary for the victims of wounds and disease in these remote places must be carried, with difficulties of which even the quartermaster's department is scarcely competent to judge. Troops are sometimes expected to live on the country; campaigns have been made that way. But no medical officer can deliberately leave to the "fortunes of war" the chance of finding medicines and instruments in the enemy's country. We can eat the barbarian's or even the savage's food, but he has no medicines.

Yet, as a rule, our troops have been provided with abundance of medicines, instruments, sterilizing apparatus, dressings, foods for the invalids, shelter and nursing. But it has not been done without constant planning, forethought, ability to adapt, strenuous endeavor, sacrifice and loyalty to duty. With moving bodies of troops or expeditionary forces, as they have been called in this campaign, the handling of the sick is naturally a more difficult problem than in even the smallest and most remote posts. Schwan's Expeditionary Force in its movements offers a typical illustration of the medical corps in action, and some remarks concerning it will best illustrate its work.

This force consisted of about 27,000 men, and moved south from Manila, Bacoor and Ismus, through Cavité province to the province of Tayabas around Lake Taal, occupying important points as it proceeded and part of it appearing on the Laguna da Bahia. Medical supplies were sent to points on Manila Bay, through which or from which the forces started, and were then transported under the supervision of medical officers in ambulances and wagons. As the region traversed became more rough and mountainous, both supplies and the sick and wounded were conveyed by Chinese coolies. These bearers were invaluable in the country impassable for the ambulance. They were economical and reliable, being useful immediately on the firing line. As the expedition debouched on the southern seacoast it was met by a hospital ship, which relieved the army of its sick and furnished fresh supplies. Thus a fresh start was practically possible. When the expedition, recurving, reached the shore of Laguna da Bahia it was met by another hospital ship, a light-draft boat, that repeated the work of the first ship.

Thus the care for the sick was most ably performed, and the column, relieved of the burden of its wounded, was rendered more mobile, a military advantage of first importance. This was also done by leaving the sick and wounded with the troops garrisoning the points held as the army proceeded. But it did not end with leaving them. Post hospitals arose as rapidly as the smoke from the camp fire; equipments and medicines were at hand by the forethought of dividing the supplies into small outfits, and relief and rest were at once afforded to those needing it. The seriously ill were rapidly sent from emergency to regimental hospitals, or to hospitals placed at points advantageous for the transportation of men and supplies.

The base hospitals, which were only converted buildings, usually of a public or semi-public character, answered well and were more fully equipped than the smaller hospitals. They have on an average a capacity of about fifty beds, and are at such points along the arteries of transportation, sail or water, that fresh supplies can be readily and frequently furnished. Here the treating of patients is necessarily an easier problem and those requiring special foods obtain them. These base hospitals are in close touch with Manila, the metropolis of the islands and the headquarters for Luzon, the largest island.



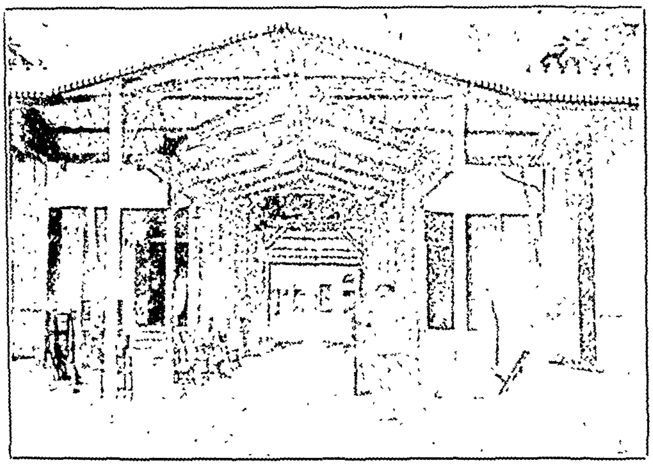
Bird's-Eye View, Convalescent Hospital, Corregidor Island, P. I.

At Manila are large general hospitals; one alone contained, at one time, 1400 patients. Here are sent patients requiring special treatment, and those from the crowded base hospitals. A receiving hospital assigns them to others of special function. Surgical cases are taken to one on an island at the entrance of Manila Bay; those convalescing from malarial fever, to another; medical cases and all diseases of the eye, to another; disabled soldiers who are to leave the service and whose disabilities are to be passed on by a medical board, and all soldiers who are to be sent to America for treatment, to another. From the latter the patients are transferred to the general hospital at San Francisco, from which point they are sent to such places as their special troubles demand or discharged from the service.

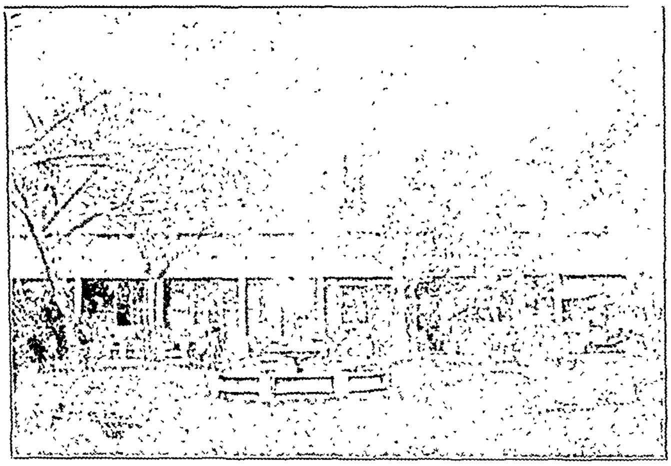
Contagious diseases are closely looked for, and few, if any, escape the hospital authorities. When a diagnosis is not clear a board investigates. All this work comes in the regular line of duty of the military surgeon.

The regular corps is at present supplemented by several hundred civil surgeons. Understanding the methods of the corps, the administrative work is naturally entirely in the hands of the surgeons of the regular army. Further assistance is rendered by the medical officers of the volunteer regiments, most of whom are permanently attached as regimental officers. As the regiments are broken up into small detachments for garrisoning, the need of a larger number of medical officers is pressingly increased. The distance between the posts is often considerable and traveling between them has, as a rule, been dangerous. In a land where physical exertion is impossible to the same extent as in the temperate zone, it requires a separate medical officer with each independent detachment that is at all removed from headquarters.

The proper work of the department is at present seriously handicapped, both by the small number of men, and further by the fact that the surgeons who are not members of the regular corps are inexperienced in the method of the department, though of sufficient professional attainments. The distribution of medical supplies is the reverse of that of forwarding the sick soldiers to the United States. With the United States as the source of supplies, through San Francisco they are shipped down to Manila as the central distributing point of the archipelago. Points accessible by water in Luzon and by the only railway are then supplied; and then the smaller posts in the respective districts of these depots, and so to the emergency hospitals.



First Reserve Hospital, Manila, P. I.—Front Entrance.



Main Entrance, Second Reserve Hospital, Manila.

The class and quantities of medicines are much different from those issued for the home troops. The diseases characteristic of the tropics require quantities of drugs scarcely used in the United States. The supplying of appropriate medicines and in sufficient quantity and in advance of the seasons when the demand for them will be the greatest, is a work calling for forethought, when we recall that many posts are cut off from all communication during the greater part of the rainy season. In Luzon, an island of some 40,000 square miles, Vigan and Aparri in the north are supplied from Manila by water communication; Angeles, in Luzon, by the railway; Nueva Caceres, in S. Luzon, by water. In the Viscayan Island Silay, Cebu and Zamboanga are the centers for their respective districts. The transportation of the sick and the supplies is supervised by the medical department, though it increases their work immensely. The character, number and quantity of supplies handled by the department is beyond belief. Medicines, foods necessary for the sick, instruments, mechanical and scientific apparatus and food, even ice, are supplied. It is hoped to equip all base hospitals with ice machines capable of an output of 3000 pounds per diem.

The medical officer is responsible for the care, discipline and existence of the soldiers who assist him in his professional duties, the hospital-corps men. Feeling the need of better trained men than the present system gives it, the department established a school for educating to a limited extent the subordinates on whom it must depend in both practical and theoretical branches. Men are assigned to a company of instruction for a period of eighteen weeks. Some fifty men are then gathered from the different districts of the department and drilled and taught theoretical and practical branches of hospital nursing, practical handling of the wounded on the field, ward work, cooking and administration of medicines. A smarter and more competent man is turned out and some bad material is gotten rid of. To those obtaining a certain degree of skill a certificate of proficiency is given at the recommendation of the officer who is acting as instructor. At present, while the company is an independent organization, it is located near Hospital No. 3, one of the largest hospitals in the islands, and the men taking this course are thus enabled to have practical instruction under close observation. Records are kept of the man's qualifications and conduct and at the end of his course he can be assigned where most needed, according to the cases for men of special aptitude or general proficiency. At the last graduation of this school these men were promoted to the rank of acting hospital steward.

This brings us to the question of nurses. The experience of the United States Medical Department is that men of greater proficiency are needed in the hospital corps, and that with the training and wages paid to female nurses they will probably be forthcoming and have the advantage of being useful with moving columns in the field as well as in the general hospitals. Indeed, in them is probably to be found the solution of the interesting question.

Still further to better combat the diseases peculiar to the climate, medical officers have been studying tropical diseases, and recently several have been named to scientifically specialize on this subject. Their studies and the results will be followed most closely and possibly a special course may be offered to the junior medical officer when he comes to this island.

The question of transportation has already been touched on but much of the actual handling of the sick is done by the medical department alone and absolutely independent of the quartermaster's department. Two ships are under the orders and immediate control of the department, which are devoted wholly to the transportation of sick, or as actual hospitals. One has a capacity of 260 beds. It is easily seen what an important factor a hospital can be in relieving pain and sickness, and also even the mobility of a column, by immediately removing its disabled and making unnecessary the detaching of troops to protect its sick and wounded. The hospital is moved to the wounded, instead of the wounded to the hospital. In an archipelago with numerous scattered ports and with independent expeditionary forces this is a matter of first importance. The conditions could be still further improved by the addition of several small light-draft vessels. The present ships, while almost perfect in equipment and of good size, are often unable to get near enough shore to enable the sick to be easily taken off.

The only railway in the islands, tapping a large area and running through the seat of the most active operations and through almost the only country not open to water communication, becomes early an important artery of transportation of men and supplies to where most of our troops were operating. A surgeon was kept on duty on the daily train and ambulances run in connection with the distributing hospitals to Manila. To facilitate the handling of the very sick, and make the trying trip more endurable, two cars were fitted up. Cots were placed in them, a closet added; a small ice-chest, medicines and cooking apparatus were carried. The trip from Manila to the end of the line is twenty-four hours in time, and the convenience and comfort to all concerned can scarcely be overestimated. Hos-

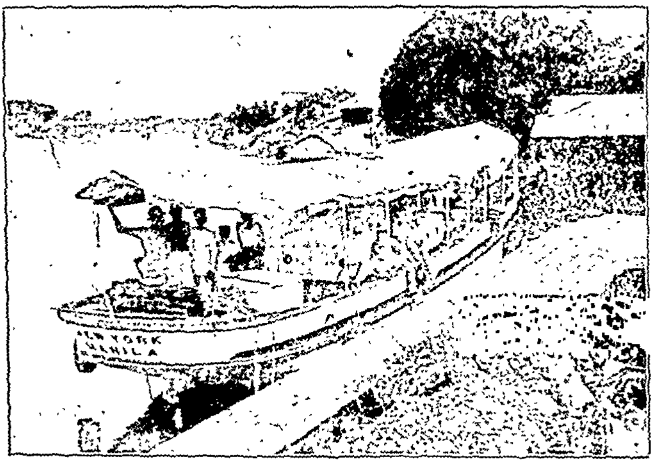
pital corps soldiers were on duty and a surgeon at hand, so all emergencies were ably met.

Among the most important and difficult of the problems met in the administrative work of the medical department are those of public vaccination. The American soldier has been vaccinated when recruited and usually also previous to this. On the long trip to the Philippines he is vaccinated again, if necessary, and frequently as a matter of precaution. When finally permanently garrisoned he is contantly under the eye of a medical officer who sees that all the men are protected against smallpox. The result is that even in a country where it is epidemic, the disease has been of little trouble or danger to the American. But to the native it is far different. The many pox-marked faces are among the first thing peculiar to the country that impress the traveler. Its ravages have been dreadful but, in spite of its being among the most frightful of diseases, the Filipino pays little attention to it. Ignorant of all prophylactic measures, except inoculation, the funerals are public, the cases are visited by friends, and the family remains living in the same hut. The fact that it has been epidemic and endemic since Europeans first visited the islands has probably rendered it less severe to the descendants of the survivors; many are protected by the disease itself. The three districts of Northern Luzon may be taken as fairly indicative of the conditions prevailing elsewhere in the archipelago, except as to the number vaccinated. This is understood when we remember that only in the districts where peace prevails is it possible to vaccinate. Even here prejudice and ignorance have hindered the work, but this is true even of England and the United States.

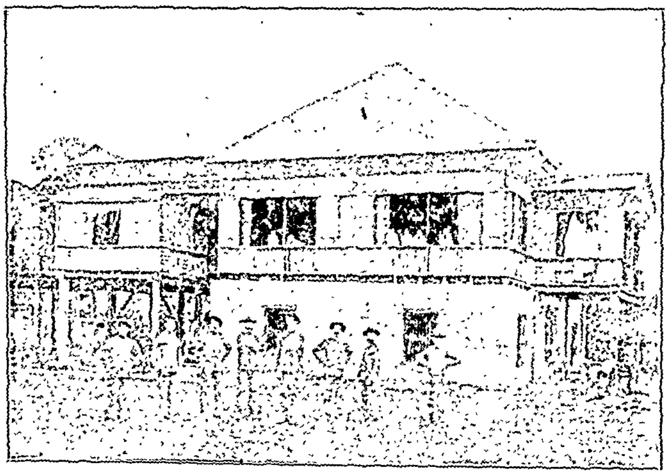


Hospital Steam Launch.

To supply the vaccin necessary for this great work the chief surgeon has established farms in Manila, and one in the southern islands. The lymph is procured from the cariboo, the indigenous water buffalo. The results, where the vaccin matter can be obtained fresh, are highly satisfactory. With the manufacture of vaccin at base hospitals, the lymph will be preserved and can be sent to all districts occupied by our troops, and the natives, as well as our troops, be protected.

It was natural to expect, under military government, that the city of Manila, the headquarters of the army, would be taken care of by the military régime, but more than that was done. Not only was the city cleaned, sewers repaired, filth removed and improvements generally instituted, but the city health was directly looked after by the medical department. A board of health was established. American quarantine officers had already taken up more thoroughly and efficiently the work formerly neglected by the Spanish régime. Practically a house-to-house inspection was made. The streets and public places had already been cleaned or work begun on them by the sanitary department. But now old vaults, dirty yards, and unhealthy places generally were ordered cleaned and the order strictly enforced. A smallpox hospital was established and cases were removed there and treated in isolation while the places formerly occupied were disinfected and quarantined and the other occupants vaccinated.

The success of the medical department in combating the scourge of the East, the black or bubonic plague, reflects most brilliantly its ability and its courage. This dread disease has been prevalent in Manila for many months, but we have yet to hear of the first case outside the city limits. The comparatively small number developing speaks well for the means adopted by the department, all of which were the most modern that science offers. The use of the odorless excavator owes its introduction in Manila to the medical department. The inspection of the abattoir, of the markets and the foods for sale in them are the civic duties in which the medical department is engaged. But this work does not stop in Manila. It is only more extensively carried on there. The same system prevails throughout the provinces occupied by our troops. Every city, village or hamlet occupied by troops is kept in the same clean condition. None are too small. The streets must be clean and the natives must not litter up the yard. The house and person of the native is, to his credit, usually extremely clean, but he is indifferent as to what his surroundings are or whence comes his water-supply. These important things are being rapidly taught them. Typhoid is endemic in the islands and garrisons have to be most careful in the selection of a water-supply.



Exterior from South End and Office, Regimental Hospital, Seventeenth U. S. I., Bautista, P. I.

Leprosy, the care of those afflicted with it, and the prevention of its further inroads, are subjects now occupying the medical department. A commission is searching for an island on which to establish a leper colony. Probably introduced from China, it has spread until there are in Northern Luzon some 12,000 (estimated) natives and Chinese afflicted with this disease. So far, it has been unrestricted, though for the relief of some of the sufferers a Chinese hospital exists. The supplies of medicines and other necessities may now be furnished. The medical officer in the isolated southern part of the island must receive the same care and attention to his applications for nurses or supplies as the one in Manila. The man in the interior of some mountainous province

The question of transportation has already been touched on but much of the actual handling of the sick is done by the medical department alone and absolutely independent of the quartermaster's department. Two ships are under the orders and immediate control of the department, which are devoted wholly to the transportation of sick, or as actual hospitals. One has a capacity of 260 beds. These important things are being rapidly taught them. Typhoid is endemic in the islands and garrisons have to be most careful in the selection of a water-supply.

Exterior from South End and Office, Regimental Hospital, Seventeenth U. S. I., Bautista, P. I.

Leprosy, the care of those afflicted with it, and the prevention of its further inroads, are subjects now occupying the medical department. A commission is searching for an island on which to establish a leper colony. Probably introduced from China, it has spread until there are in Northern Luzon some 12,000 (estimated) natives and Chinese afflicted with this disease. So far, it has been unrestricted, though for the relief of some of the sufferers a Chinese hospital exists. The supplies of medicines and other necessities may now be furnished. The medical officer in the isolated southern part of the island must receive the same care and attention to his applications for nurses or supplies as the one in Manila. The man in the interior of some mountainous province must have his supplies before the rains have made transportation impossible.

The position of chief administrative officer of this department calls for abilities equal to those necessary to the successful manager of a railroad system or a great industry. But it is not a question of profits that is the splendid reward, nor is it an independent personal fortune. The tremendous responsibilities are assumed for a modest salary.

This hurried recital of the work of the United States Medical Department in the Philippines will probably introduce to the practitioner at home duties he had never dreamed of as belonging to this corps.

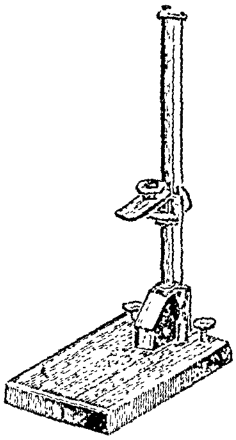
It would require a paper in itself to tell of the work the medical officer is doing among the natives of the islands in numerous little villages. The treatment of the sick, the government's generous distribution of medicines and food can not fail to elicit some feeling of gratitude, and moreover the sanitary measures will not fail to protect him and his family. The medical department will not be the least useful instrument employed in making Luzon a second Java.

A NORMAL ACOUMETER.*

E. AMBERG, M.D.

DETROIT, MICH.

If the eyes of a patient have been examined he may receive a certificate and go to any country with his ophthalmic passport. It is different with the ear.



Amberg's Acoumeter—One-fifth Natural Size.

The voices of different men vary, and instruments, which are precisely alike and can be used in precisely the same way by various examiners, do not exist. Even Politzer's acoumeter is not exempted, in my opinion.

After careful consideration of the merits of Politzer's instrument, I am convinced that the limit of exactness is not reached therein. In the first place it is too complicated to give a guarantee that all acoumeters can be constructed exactly alike, and there is a possibility that the same instrument produces different effects at different times, if differently handled by the examiners. For instance, the effects of elasticity are not entirely barred. Although the question may arise whether for our work those delicate discriminations should be considered, I am of the opinion that from a scientific point of view, if not from a practical one, we should have our instruments as exact as they can possibly be made.

Guided by a desire to have, at least for air conduction, an apparatus which excludes the possibilities of error as much as possible, I had one constructed, in Berlin, by Heele, maker of precision-instruments, which in my mind excludes errors to a greater extent than Politzer's acoumeter does. The principle of this apparatus is an old one. A steel ball of a certain weight, in this case of one gram, falls through a certain distance on a metallic block. The weight can be made absolutely correct. The surface, as to constitution and direction, can also be made absolutely correct; as the manufacturer told me metal of the same character can be procured at any time.

A similar instrument is used, for instance in psychophysical laboratories, in order to test the depth of sleep. I mentioned this fact some time ago when referring to my instrument on another occasion.

The conditions for examination can be changed, either by placing the apparatus at various distances from the patient's ear, or by changing the height from which the steel ball has to fall. I should like to suggest that, in comparing records, either the plan be adopted to place the instrument one or two meters from the patient's ear and to record the height, or else that the instrument may be moved and the distance recorded when the steel ball falls a certain number of millimeters.

I believe that Jacques Loeb has had experiments made on the ear with the aid of a similar instrument. I became acquainted with this fact after my apparatus had been constructed. The value of my apparatus consists in the fact that the instruments can be made so that they do not differ one from another.

32 Miami Avenue.

AMBLYOPIA FOLLOWING THE INTOXICATING USE OF JAMAICA GINGER.

SUBSEQUENT RECOVERY OF VISION.*

EDWARD STIEREN, M.D.

PITTSBURG, PA.

A careful search through American ophthalmic literature reveals eight recorded cases of blindness following the ingestion of ginger. One case is reported by Archibald G. Thompson,[1] of Philadelphia. Asst.-Surgeon J. B. Greene reports[2] a case which appears to be one of the six carefully reported cases of Hiram Woods,[3] of Baltimore.

The history of my case is as follows:

N. C. R., aged 36, contractor and builder, was first seen Sunday evening, Oct. 15, 1899, and appeared totally blind, requiring the services of a friend to lead him about.

He had been drinking heavily on Saturday and, on sobering up Sunday morning in a "dry" community where no liquor of any kind could be obtained, purchased from a storekeeper a box of a dozen bottles of Jamaica ginger, each containing about an ounce. The entire dozen were consumed before noon, the first four bottles diluted with water, the remaining eight undiluted. About noon he dropped into a drunken stupor, and awoke about 3 p. m. totally blind, but with no other untoward symptoms, except a consuming thirst. His alarmed cries brought friends to his assistance; they brought him to me about 6 p. m.

Examination revealed the following conditions: Pupils widely dilated, and unaffected by light or accommodation; conjunctiva slightly injected; media clear:

[1] Ophthalmic Record, November, 1897.

[2] Annual Report of the Supervising Surgeon-General of the U. S. Marine-Hospital Service, 1898.

[3] Ophthalmic Record, February, 1899.

no change whatever in disc or vessels, and beyond a slight blurring of edge of disc due to slight retinal edema, fundus of each eye was normal. Vision was almost nil; he could see hand moved at twelve inches. Cornea was almost totally insensitive to touch with camel-hair pencil.

Treatment consisted in immediate confinement to bed in a darkened room. Three hot foot-baths were given during the night, and 20 grs. each of calomel and compound jalap powder in divided doses. He received ⅛ gr. pilocarpin muriate hypodermically twice during the night.

This treatment caused active diaphoresis and catharsis, and at 9 o'clock the next morning patient was able to count fingers with each eye at ten inches.

The pilocarpin was continued, ⅛ gr. hypodermically at intervals of six hours, and calomel in 1 gr. doses every two hours for the next two days, when the pilocarpin was discontinued and 20 gr. doses of potassium iodid supplanted the calomel, slight tenderness of the gums occurring.

Patient's vision continued to improve, and on the fifth day he was allowed to come to my office; vision in each eye was 20/30. At no time was there any change in the ophthalmoscopic picture. His field of vision could not be obtained when first seen, but in the second office-visit, the fifth day after his indiscretion, no scotoma nor narrowing of the field could be demonstrated. Pupils reacted strongly to light and accommodation. He could read J. No. 1 with an effort, and read No. 4 readily. He has 1 D. hypermetropia with which, corrected, vision in each eye = 20/20.

I have seen this patient from time to time since his acute attack of blindness and, having been thoroughly frightened, he has totally abstained from alcoholic stimulants. His ocular condition remains the same as above noted. I saw him last, March 27, and obtained from him a negative history in regard to syphilis. He uses tobacco in moderation, and before his sudden attack of blindness, was a periodic alcoholic, going on a spree about once every six weeks and which usually lasted three to four days.

I believe, with Thompson and Woods, that the lesion in these cases is an acute retrobulbar neuritis, and that it is of a toxic nature.

The sudden onset in an individual who had practiced alcoholic indiscretions periodically for a number of years without any evil effects to his eyes, and who then becomes suddenly blind after drinking an enormous quantity of an irritating essence containing volatile oils, resins, and a questionable form of alcohol, inclines me to believe in the toxic factor in producing the neuritis. This belief is further strengthened when prompt eliminative measures are followed by improvement and cure.

THE DOUCHE IN THE TREATMENT OF OPHTHALMIA NEONATORUM.*

E. E. HOLT, M.D.
PORTLAND, ME.

On May 22, 1899, Dr. Fuller, of Bath, sent me an infant suffering from ophthalmia neonatorum. Dr. Fuller had been called in consultation to see the baby in Richmond and found it in such a critical condition that he advised having it taken to me at once. The baby was between two and three weeks old, and the disease had developed into a critical condition. There was a profuse purulent discharge issuing from both eyes, and so much chemosis and swelling of the lids that it was difficult to make a satisfactory inspection of the cornea of either eye; it was finally determined that the cornea was involved and about to break down in each eye.

The mother was making a supreme effort to save the sight of the child, having recently left her bed to make the journey to Portland. She was delicate, exceedingly nervous, but intelligent and anxious to do anything to save some sight for the child. As she was nursing the child I assured her that it was absolutely essential for her to compose herself in order to give her baby the best chance for recovery. This she did in a heroic manner; cow's milk was given in addition to that of the mother's. On carefully considering the case it did not seem to me that continuing the ordinary methods of treating eyes in such cases would preserve much sight for the child; but it occurred to me that if the eyes could be thoroughly douched and all the secretions from the conjunctiva kept constantly washed away there would be some chance of saving sight. Acting on this suggestion I took a Davidson syringe, and with the No. 1 point I pressed it between the lids at the outer canthus and threw a stream of tepid water containing about 1 per cent. of boric acid until I had used a quart or more for each eye. The point of the syringe was always directed away from the eyeball and was gradually worked along the whole length of the retrotarsal fold so that the conjunctival sac was thoroughly washed out. The douching of the eye was repeated every half hour, night and day, for the first twenty-four hours; then less frequently and at the end of the fifth day the baby was opening its eyes and looking about the room. This was certainly a revelation to me and the nurses who were familiar with the usual methods of treatment, and had witnessed the rapid change.

The cornea cleared, recovery was complete and the mother went home with all the happiness that could come from such a rapid and unexpected result.

The same method of douching has been carried out on other cases in about the same critical condition with the same happy result.

In the first case cited a 2 per cent. solution of nitrate of silver was used from the first and the eyes were cleansed by irrigations, pipettes and absorbent cotton. When the child came under my care the 2 per cent. solution of nitrate of silver was continued daily, care being taken that it did not reach the cornea; cold packs were applied to the lids between the intervals of douching, and the nourishment of the child was given all the attention possible.

All authorities are agreed that cleanliness is of the highest importance, but I fail to find any mention of the douche to accomplish this result. The douching may be carried out by the use of the fountain syringe, but I prefer the syringe like that known as the Davidson where the force of the stream can be increased or diminished at will. For the purpose of accomplishing the douching, especially at the beginning of the practice, I have had the Davidson Rubber Company make me a hook-like point which has several openings at its end that may be attached to the syringe and used instead of the No. 1 point that comes with the syringe.

I believe that the douche properly carried out will be as efficient to check the disastrous course of those cases of purulent conjunctivitis which have arrived at the critical condition here described as Credé's method is in preventing them from reaching this critical condition.

SATURDAY, JANUARY 5, 1901.

THE PAST AND THE FUTURE.

With this issue we begin a new year and a new century. That just closed has been without parallel in the world's history in its material and scientific advances, and our science and our profession have not been the least sharers in the progress. The surgery of the beginning of the 19th century, as a distinguished authority has said, was nearer to that of the times of Hippocrates than to that of the present day, and the same is little less true of medicine in general and its related sciences, though the fact may not be so immediately apparent. In no corresponding period of the world's history as we know it, have there been so many epoch-making discoveries and so marked a general advance.

The medicine of 1800 was hardly less antiquated than its surgery, when compared with that of the present day, and this difference is not a matter of fashion or convention, but a scientific advance that stands the tests of time and experience. The marked prolongation of human life at the present time, over that of the 18th century or the beginning of the 19th, is of itself ample proof of the advance of medical science to which the science of hygiene owes its growth.

There is still another side to the shield, however; with all the progress of the past and present, there are still the old problems of death and disease to be met by our profession and some that are brought before us by the special conditions of our modern civilization. The world has, in a sense of the term, grown smaller and to the diseases of civilization through the increased and universal facilities of intercourse, we have to meet those of barbarism also. At the present time we are in the presence of a pandemic of plague, which has already invaded regions where it possibly was never known before, and we do not yet know what the outcome may be, though we do not fear a repetition of the wholesale epidemics of the past. There is occurring, apparently, a recrudescence of leprosy that threatens civilization, and it is to be expected that other disorders may extend their range and call for our serious attention if they do not materially affect our mortality rates.

What will be the problems and achievements of the coming century no man can prophesy and it would be rash to assume that equal progress will or will not be made. There are some who apparently believe that we shall solve all the mysteries of life, but they may be very much disappointed. What may be reasonably hoped for is a continuation of progress along the lines already opened, a greater perfection in technique, diagnosis and treatment, a widening of our pathologic knowledge, increasing acquaintance with the natural processes and remedies for disease, a better prophylaxis, and more than for anything else we should strive for a broader and deeper culture in our profession that will enable it not only to accumulate facts and originate theories, but to properly estimate them and utilize them.

That medicine starts in on the new round of years, greatly in advance of the position it occupied 100 years ago, is unquestioned. It has kept well abreast with the progress achieved in other fields of human endeavor. While marked by less productiveness and originality than in older countries yet American medicine during the nineteenth century has passed through a remarkable development fairly commensurate with the marvelous material progress of this country. During the nineteenth century things were achieved in medicine that were unknown and undreamt 100 years ago. But there are abundant unsolved problems left for the twentieth century to solve, and in the light of the achievements of the century just ended it is permissible to predict that great revelations are in store. During the coming years the productive activity now apparent in American medicine is bound to increase. The opportunities for investigation were never quite as promising as now. A new spirit—the university spirit—is beginning to make itself felt and to direct developments in medical education, and a corresponding elevation of standards in all lines of work is already apparent.

While assured that American medicine in the twentieth century will take an active part in the advancement of medical sciences, the sociologic relations of medicine in this country offer problems of great importance. There is need above all things for a greater public faith in the teachings and the advice of the medical profession in matters relating to hygiene and to the prevention of disease. Hygiene should dictate to legislators and courts of law and not economic interests alone. "Unfortunately on the human race there still weighs that fate by which both preventable diseases and premature deaths, as well as duration of life itself, essentially depend on economic institutions." There is hope that the twentieth century may witness great improvements as knowledge is disseminated and the mass of the people learn to place confidence in medical teaching.

The medical college in the coming century will have to give more attention to the quality than the quantity of its output, if present signs are not misleading. Human nature will not change; there will still be deceivers and their followers, but this will only accentuate the demand for higher qualifications in our profession. The future of science is not in doubt; the world will not stop in its progress nor loose what it has gained, but the future of the medical profession is in its own hands and can only be assured by its living up to its higher ideals.

be a loss. While it is reported that the *Philadelphia Medical Journal* has sunk a large amount of money in the three years of its existence, this does not reflect on the editorial management, but rather on the lack of business sagacity of those who put money into it. It does not require much of a mathematician to figure up the cost of paper, press-work, typesetting and postage; there need be no guess work about this. And when to these figures are added the other expenses connected with such an enterprise, which can be fairly well estimated, it ought to have been known that at the price charged a loss must result. If such a losing enterprise affected only those who backed it financially, it would be a serious matter to them alone, but in this instance it has a demoralizing effect on legitimate medical journalism.

THERAPEUTIC NIHILISM.

Optimism, not pessimism, is needed in medicine; not. however, the optimism that takes up each new fad to the exclusion of old and tried measures, but the kind that begets hopefulness and confidence. There is a tendency, among a few, to therapeutic nihilism that is to be regretted. He who has watched a huge cardiac edema subside under the intelligent administration of digitalis, or who has seen an angry tertiary syphilid fade away under full doses of potassium iodid, or, above all. who has seen the threatening false membrane of diphtheria shrivel and fall after the use of antitoxin can never honestly express a disbelief in the benefits of modern therapeutics. Those who are yet opposing the use of antitoxin argue chiefly from *a priori* reasoning. The men who are treating diphtheria with antitoxin and who are old enough to compare their own results under the old means with those since they began to employ the new, have another tale to tell. The therapeutic nihilist has no place in modern medicine; now the science of therapeutics is becoming thoroughly rational. Profession of disbelief in measures for aiding in healing of disease is a confession of personal failure in practice. The fault is in the man, and not in the method. Many diseases yet baffle us, and many of our agents are not yet perfect, but the spirit that will lead to a better state of affairs is only that of hopefulness and of belief in the capacity of medical science to grow until more and more diseases are conquered.

THE TOXIC EFFECTS OF FORMALDEHYDE (FORMALIN).

The general use made of formaldehyde—especially in the form of the commercial 40 per cent. solution in water, known as formalin—as a disinfectant, as an embalming fluid by undertakers, and in histologic laboratories makes the experimental study of its toxic effects desirable. In a preliminary communication, Martin Fischer[1] shows that the inhalation of formaldehyde produces a marked inflammation of the respiratory tract. Injections into the stomach produce a variety of symptoms, and even sudden death; apparently the intensity of the symptoms and the degree of histologic disturbances bear no direct relation to strength or quantity of formalin introduced. Intense congestion, extensive necrosis and inflammatory reaction occur. Intraperitoneal injections produce a fibrino-hemorrhagic peritonitis of varying intensity, according to the strength of the solution. Subcutaneously injected, formalin produces a marked exudation and leucocytic infiltration. The eye is especially sensitive to the action of formalin. A single drop of concentrated formalin may injure the eye permanently, due largely to an intense edema of the eye-lids, which are prevented from closing. Various degenerative changes and focal necrosis are seen in the liver and the kidneys, no matter where formalin is introduced into the body. The leucocytic infiltration after the introduction of formalin is characterized by the eosinophiles appearing the first, followed by other polymorphonuclear forms, the small mononuclears appearing last. Fischer believes that osmotic disturbances are to be held accountable for the exudation and the cellular necrosis. Deleterious chemical action causes the changes seen in organs distant from the point of injection. A substance as active as formaldehyde, and in so general use, is of much toxicologic importance and, judging from Fischer's experiments, it certainly behooves all that employ this substance to exercise the greatest care, lest serious accidents happen.

LAY MANAGEMENT OF MEDICAL INSTITUTIONS.

It is a common practice of politicians, and sometimes also of lay professional philanthropists and others, to charge physicians with a lack of business or so-called executive ability and to therefore insist upon lay management of medical institutions. It is very exceptionally the case that facts justify this assumption, while a very large number of cases can be cited where lay management is unbusinesslike and even disastrous. The needs of a medical establishment, and especially of a hospital, can only be fully appreciated by a medically-educated man, and it often happens that while finances may be economically administered, the real purpose of the charity is to a greater or less extent frustrated by the ignorance or obstinacy of its lay administrators. Even this judicious management of funds is not the universal rule and the worst financial scandals occur under just such conditions. The *Medical Press and Circular* editorially mentions an instance of fatuous financing of a public charity by lay managers that strikingly illustrates this point. The oldest and best known ophthalmologic hospital in Great Britain, until recently, occupied freehold premises of immense and increasing value. On the plea that they were inadequate the committee sold the premises, transferring the hospital to grounds involving a yearly rental of thousands of dollars and heavy taxes. Then they sank the amount derived from the sale of their old site in their new building and deprived the hospital of apparently its only permanent asset. It is said, moreover, that the charities commissioners will require that the value of the site be made up within a definite period, thus making an additional charge upon the hospital. Altogether it appears to be about as bad a piece of financing a trust as can well be imagined, but it is not without its counterparts. Medical administrators may have their faults, but they could hardly be worse than their lay confrères; they have, moreover, what the others lack, a professional in the clinical signs, with diminution in the amount of expectoration and disappearance of tubercle bacilli from the sputum.

---

[1] Journ. Boston Soc. of Med. Sc., 1900, v, 18-22.

We have no wish to be pessimistic, but a rather disappointing experience has taught us not to expect too much from any method of treatment for pulmonary tuberculosis that has not been on trial for years and has sustained its early reputation. Too often have we read reports almost identical with those cited, but time has merely proved the fallacy of generalizing upon insufficient experience. Besides, we doubt if the intravenous method of treatment will ever become a popular or even generally commendable one, as it offers numerous opportunities for grave accidents. We are hopeful that a specific for tuberculosis will yet be discovered, and we believe that it will be of biologic origin, but it must be borne in mind that the infection in cases of pulmonary tuberculosis often becomes early a mixed one and we may then have to do with serious complications. The treatment, therefore, will always have to be general and be directed both to the constitutional state as well as to the local lesion.

DISEASES FROM VEGETABLES.

Some time ago The Journal[1] noticed editorially an epidemic of typhoid in an eastern institution that was traced to eating raw celery, and incidentally pointed out the possible dangers of eating uncooked garden vegetables. Quite recently a series of observations have been made by Professor Gualdi, of the Bureau of Hygiene, at Rome, on the relations existing between the occurrence typhoid and the consumption of raw vegetables. As orted in the Rome correspondence of *The Lancet,*[2] e finds a close connection between the two, the seasonal curve of typhoid corresponding very closely to that of the quantity of such vegetables sold in different months of the year. Neither the water-supply nor milk contamination are able to satisfactorily explain the facts that can be accounted for in this way.

At Padua a careful and extended microscopic and bacteriologic study of garden vegetables has also been carried out by Professor Ceresole which clearly demonstrates their importance as typhoid-producers. After first thoroughly washing them with the excellent local aqueduct water, the vegetables—lettuce, endives, radishes, fennel and celery—to put them in the condition in which they are usually eaten, they were cut up fine with sterilized scissors and placed in a flask of distilled and sterilized water. After a thorough shaking the water was examined microscopically and bacteriologically. The microscopic examination revealed, besides a host of innocuous forms, ameba coli, balantidium coli, isotrica prostoma and anguillula stercoralis, together with eggs of tenia, oxyuris, ascaris, trichocephalus and ankylostoma. The bacteriologic examination revealed such a host of species that identification of every one was impracticable, but among them were found bacillus coli, septicus, tetani, and a form indistinguishable from B. typhosus. Six animals inoculated with washings, after they had been some minutes heated, all died, five from malignant edema and one from tetanus. Four animals were inoculated with washings not heated, one died with malignant edema, one with tetanus and the other two had locally at the point of inoculation large abscesses from which pure cultures of streptococcus and staphylococcus were obtained.

If vegetables elsewhere are at all comparable, as regards their pathogenic associations, with those of Italy, vegetarianism ought to be at a discount and most of us would do well to make our wills. It is probable that germs enough abound and that we occasionally suffer from their activity; certainly there is good reason to be cautious in eating uncooked vegetables. The fact that ordinary washing is not sufficient to destroy or remove them, as is indicated by Professor Ceresole's experiments, is important, as is also the fact that he states that a half-hour's soaking in a 3 per cent. solution of tartaric acid—about one ounce to the quart of water—is an efficient disinfectant. The danger is one worthy of investigation and while it is not so imminent as it might appear, since most of us must have acquired a certain degree of immunity, yet the products of the truck gardens in the vicinity of large towns, particularly in continental Europe, are not above suspicion of contamination of a possibly dangerous type. It would be well for those investigating obscure causes of epidemics of typhoid to bear in mind this possible causation.

MOB LAW IN COLORADO.

The Denver *Medical Times* for December contains as its editorial leader a lucubration which, though its title is "Mob Law in Colorado," in tone is distinctly apologetic for the recent atrocious lynching where a negro was burned at the stake. If the lack of provision for capital punishment in Colorado's laws involves the alternative of such occurrences, the sooner hanging is reinstated the better; there ought to be no lack of executioners since so large a portion of the community are willing to volunteer not merely as hangmen, but as torturers. The proceeding was a disgrace to the age and to the state, and while we can recognize the possibility of a temporary delirium affecting the community, its late condonation has not even this excuse.

EDITORIAL CHANGE IN THE PHILADELPHIA MEDICAL JOURNAL.

Dr. George M. Gould has retired from the editorship of the *Philadelphia Medical Journal,* Drs. John Hendrie Lloyd and Julius L. Salinger assuming charge of the editorial management. This announcement will be a surprise to most of our readers, as it was supposed that Dr. Gould was inseparably connected with that journal. We doubt, however, if he will stay out of medical journalism long, as it is a work he loves and for which he is well fitted. He has always stood for high ideals in medicine and medical journalism and his continued absence from the editorial ranks would be a loss. While it is reported that the *Philadelphia Medical Journal* has sunk a large amount of money in the three years of its existence, this does not reflect on the editorial management, but rather on the lack of business sagacity of those who put money into it. It does not require much of a mathematician to figure up the cost of paper, press-work, typesetting and postage; there need be no guess work about this. And when to these figures are added the other expenses connected with such an enterprise, which can be fairly well estimated, it ought to have been known that at the price charged a loss must result. If such a losing enterprise affected only those who backed it financially, it would be a serious matter to them alone, but in this instance it has a demoralizing effect on legitimate medical journalism.

Deleterious chemical action causes the changes seen in organs distant from the point of injection. A substance as active as formaldehyde, and in so general use, is of much toxicologic importance and, judging from Fischer's experiments, it certainly behooves all that employ this substance to exercise the greatest care, lest serious accidents happen.

LAY MANAGEMENT OF MEDICAL INSTITUTIONS.

It is a common practice of politicians, and sometimes also of lay professional philanthropists and others, to charge physicians with a lack of business or so-called executive ability and to therefore insist upon lay management of medical institutions. It is very exceptionally the case that facts justify this assumption, while a very large number of cases can be cited where lay management is unbusinesslike and even disastrous. The needs of a medical establishment, and especially of a hospital, can only be fully appreciated by a medically-educated man, and it often happens that while finances may be economically administered, the real purpose of the charity is to a greater or less extent frustrated by the ignorance or obstinacy of its lay administrators. Even this judicious management of funds is not the universal rule and the worst financial scandals occur under just such conditions. The *Medical Press and Circular* editorially mentions an instance of fatuous financing of a public charity by lay managers that strikingly illustrates this point. The oldest and best known ophthalmologic hospital in Great Britain, until recently, occupied freehold premises of immense and increasing value. On the plea that they were inadequate the committee sold the premises, transferring the hospital to grounds involving a yearly rental of thousands of dollars and heavy taxes. Then they sank the amount derived from the sale of their old site in their new building and deprived the hospital of apparently its only permanent asset. It is said, moreover, that the charities commissioners will require that the value of the site be made up within a definite period, thus making an additional charge upon the hospital. Altogether it appears to be about as bad a piece of financing a trust as can well be imagined, but it is not without its counterparts. Medical administrators may have their faults, but they could hardly be worse than their lay confrères; they have, moreover, what the others lack, a professional interest in their charge and we believe also, as a rule, a feeling of professional honor, which is a better insurance of honest administration than much of the average business principles extant. It may be that sometimes these latter, as our English contemporary strongly hints, are not used to the best advantage of medical trusts confided to the care of business men.

PROFESSIONAL APATHY.

The *Practitioner* editorially bemoans the apathy of the majority of the members of the medical profession. As an illustration it cites the annual meeting of the Fellows and Members of the Royal College of Surgeons, of England, at which only ten of the 1300 Fellows and less than three-score of the 17,500 Members thought it worth while to attend. The meeting is characterized as representing nothing "but the total indifference of the body corporate to the affairs of the College." As a remedy it recommended, and wisely too, that the members be given a share in the management of the College, which it seems that they do not have now. By so doing it is hoped that the members may be roused from the apathy that now delays and hinders the removal of grievances and disabilities of the medical profession in England. This goes to illustrate that in this case, as in so many others with which we are more directly familiar, it is largely the fault of the physicians themselves that the "well-being of the medical commonweal" is allowed to suffer neglect. How many a time throughout our various states has not a worthy cause of vital interest to the medical profession been ruined by careless advocacy? Whenever the medical profession joins its efforts in a movement concerning the earnestness of which there is no doubt it is quite sure to carry its point. As indicated by the *Practitioner*, in commenting on some remarks in The Journal for November 3, on "Medical Men in Politics," "is it not mainly the fault of the doctors themselves that they are so poorly represented in the legislative councils?"

THE BACTERIOLOGY OF YELLOW FEVER.

Walter Reed and James Carroll have made a comparative study of the biological characters and pathogenic actions of bacillus X of Sternberg, bacillus icteroides of Sanarelli, and the hog cholera bacillus.[1] The results will be of much interest to those who have followed the controversy in regard to the etiology of yellow fever, which has been going on for some time between these authors and Sanarelli. Reed and Carroll conclude that Sternberg's bacillus X belongs to the colon group, and that Sanarelli's bacillus icteroides, proclaimed by its discoverer to be a cause of yellow fever, is a member of the hog-cholera group, because the various channels of infection, the duration of the disease and the gross and microscopic lesions in mice, guinea-pigs and rabbits are the same for B. icteroides and the hog-cholera bacillus. Comparison of the cultural characteristics also indicate that bacillus icteroides should be put among the hog-cholera group of bacteria. The hog-cholera bacillus of Salmon and Smith and bacillus icteroides produce the same clinical symptoms and anatomical lesions by intravenous injections in dogs. Bacillus icteroides, when fed to domestic pigs, causes fatal infection with diphtheritic, necrotic and ulcerative lesions in the digestive tract, such as are seen in hog-cholera. Guinea-pigs may be immunized with sterile cultures of bacillus icteroides from a fatal dose of the hog-cholera bacillus and vice versa; and rabbits may be immunized from a fatal dose of the hog-cholera bacillus by increasing doses of living cultures of bacillus icteroides. Serums of animals immunized with bacillus icteroides and with the hog-cholera bacillus, respectively, show a marked reciprocal agglutinative reaction. The blood of yellow fever practically does not exercise an agglutinative reaction upon bacillus icteroides, while the blood of hog-cholera agglutinates this bacillus in a much more marked degree. Add to this the fact that bacillus icteroides may be absent from the blood of yellow-fever patients during life and from the blood and the organs after death, and it seems quite evident that bacillus icteroides can not be regarded as bearing any closer relationship to yellow fever than that of an occasional secondary invader. The essential outcome of the matter is that the etiology of yellow fever is still an unsolved problem.

POLYMYOSITIS.

Although inflammation of muscle is not a rare complication of other diseases, it is exceedingly uncommon as a primary and independent affection. It is likely that the muscular involvement of acute rheumatism is inflammatory in character, and it may be that a part of what we are accustomed to designate subacute or muscular rheumatism and some forms of myalgia are also of like nature. It seems, further, not impossible that some cases diagnosed neuritis are complicated by, if not primarily a condition of, myositis. Some difference of opinion prevails as to whether the several varieties of primary muscle-inflammation are identical in character, though differing in degree—dependent upon the same cause, and the symptomatology varying with the virulence and the volume of the infecting agency on the one hand and the susceptibility of the individual attack on the other hand—or, whether the etiology is diverse and multiple. A clinical and pathological distinction can be made between purulent and non-purulent myositis; and of the latter, three varieties can be recognized, namely, *dermatomyositis, hemorrhagic polymyositis*, and *polymyositis associated with multiform erythema*. To the small number of cases of acute hemorrhagic polymyositis on record Struppler[1] adds the report of another, occurring in a laborer, 33 years old, and terminating fatally from edema of the larynx in the course of six days. The onset was sudden, without prodromes, and the clinical manifestations included articular pain, moderate elevation of temperature, profuse sweating, increased pulse-frequency, cutaneous hemorrhage, tumefaction and infiltration of various muscles of the upper and lower extremities, with slight superadjacent doughy edema, glossitis, angina, edema of the larynx and fibrinous pleurisy. Post-mortem examination disclosed polymyositis of the supinators and extensors of both arms, with hemorrhagic extravasations in the muscles and the skin and in the palatopharyngeal arch, the peritracheal tissues and the lungs. The heart was not involved. The spleen was slightly enlarged. Struppler reports also a case of recurrent acute rheumatic polymyositis associated with multiform erythema, occurring in a painter, 24 years old, with involvement of the frontal muscles and the left temporal muscle, which suddenly became the seat of a tender edematous swelling, in addition to the gastrocnemii and the right peroneus brevis.

Medical News.

CALIFORNIA.

DR. JOHN FIFE, Red Bluff, has been appointed physician of Tehama County at a salary of $80 per month.

THE POSITION of health officer of Humboldt county was abolished by the supervisors, December 12. What the county will do after January 1 without a health officer is a matter of conjecture and even the supervisors who abolished the office are ignorant as to the outcome of their order.

THE CALIFORNIA HOSPITAL, Los Angeles, at the annual meeting of its stockholders, December 18, elected Dr. Fred T. Bicknell, president; Dr. Everett R. Smith, vice-president; Dr. Walter Lindley, secretary and manager, and Dr. William W. Hitchcock, treasurer. During the two years and four months since the hospital was opened, 2325 patients have been treated, and the capacity of the institution has been nearly doubled in the last year, by the construction of an annex.

THERE IS TROUBLE in San Francisco because the Pacific Coast Regular College of Medicine, a night medical school, incorporated in May, 1900, proposes to graduate seven students this month. It is claimed that 2 of the 7 would-be graduates have no certificates showing that they have taken the requisite courses of study and passed the required examination. There is nothing in the law of California to prevent any enterprising person from incorporating himself and a few of his friends as a medical college and thereafter issuing degrees after compliance by the graduates with such requirements as may seem to suit him best. Dr. Dudley Tait, of the State Board of Examiners, says he will oppose the granting of licenses to the graduates of this school.

PLAGUE REPORT.

The case of a man residing at 844 Washington street, with suspicious symptoms of plague, was reported to the health office on December 6. Dr. Kellogg, the city bacteriologist, saw the man at 4.30 p. m. of that day with Drs. Morrissey and Pratt. They found a Chinaman, named Lee Ho, in a comatose condition, pulse 146 and very weak. The temperature was not taken, but the man's body was very warm to the touch, while the extremities were cool and cyanotic. There were no petechiæ in the skin. There was a very large and tender bubo in the left femoral region. Blood would not flow from the ear, but the bloody fluid secured by aspiration of the bubo showed numerous plague bacilli. The people in the house could give no intelligent account of his illness, but said he had been sick only six days. The patient died the next morning at 10 a. m. and Dr. Kellogg performed an autopsy on the afternoon of the same day, Drs. Rykfogel, Kinyoun, Wilson, Morton, and Brown being present. The subject was a well-developed, well-nourished medium-sized male. The heart and lungs were normal, the right lung being bound down by extensive adhesions. There was about 15 c.c. of blood-tinged serum in the pericardium, and about 60 c.c. in each pleura. The liver was fatty. The spleen was about twice its normal size, dark red and soft, a cut section showing whitish specks scattered over its surface. The kidneys were normal in size, dark in color, and considerable fluid blood exuded from their cut surfaces. Their capsules stripped easily. The mesenteric glands were slightly enlarged. The small intestines contained a few submucous hemorrhages. The diagnosis in the case of Lee Ho has been fully confirmed by inoculating animals with a pure culture obtained from his blood the day before he died. The guinea-pig died in three days with typical plague lesion, and the organism was obtained in pure culture from its spleen.

COLORADO.

DR. WILLIAM L. KELLER, acting post-surgeon at Fort Logan, Denver, has been assigned to duty in the Philippines. He has been succeeded by Dr. Louis Brechemin.

DR. MARY KAVENY, Denver, who recently brought suit against Dr. Clayton Parkhill, for $10,000 damages, because of an alleged shortening of one quarter of an inch in a leg treated by him, has refused to allow X-ray photographs to be taken of the leg, and in consequence the suit will probably be dropped.

THE SECRETARY of the State Board of Health states that there are 50 cases of smallpox in El Paso county, 16 in the Cripple Creek district, 25 in Pueblo, 20 in Denver and 10 in Clear Creek county. There are also scattering cases in nearly all the mining camps. Extra precautions are being taken by the local health boards.

CONNECTICUT.

TWO NEW HAVEN PHYSICIANS, Percy D. Littlejohn and Alfred G. Nadler, have offered their services as medical examiners in the public schools, free of charge.

THE COMMISSION appointed by the National Association for the Study of Epilepsy, to collect statistics relative to the malady and to assist in a movement to establish a state asylum for epileptics, consists of Drs. Frank K. Hallock, Bridgeport; Max Mailhouse, New Haven, and Edwin A. Down, Hartford.

THE GENERAL HOSPITAL SOCIETY of Connecticut has agreed to allow Yale University to erect a clinic building for its medical school, on the hospital grounds, in New Haven. The building will cost $3500 and is to be used by professors and instructors of the medical school. The university will pay a small rent for the current expenses of the building.

THE HARTFORD HOSPITAL held its annual meeting December 19 and announced the following changes in its staff: Dr. Frederick T. Simpson becomes consulting physician and surgeon; Dr. Everett J. McKnight succeeds the late Dr. Melancthon Storrs as visiting surgeon, and Dr. Walter R. Steiner is appointed pathologist and bacteriologist in place of Dr. John B. McCook, who is made assistant surgeon.

DELAWARE.

SURGEON HIRAM W. AUSTIN, U. S. M.-H. S., has been appointed medical officer in charge of the national quarantine service on the Delaware river and bays, which includes the quarantines at the Delaware Breakwater and Reedy Island.

THE MEDICAL EXAMINING BOARD, representing the president and fellows of the Medical Society of Delaware, met at Dover, December 11, 12 and 13, to examine candidates for licenses to practice medicine and surgery in the state. Seven candidates appeared.

THE RESULT of the execution of the law regulating the practice of medicine and surgery in the state is shown in the report of the medical examining boards for the year. Of regular medical colleges, 61 graduates applied; of homeopathic colleges, 13. The failures to pass occurred in the cases of 14 regulars and 1 homeopath.

ILLINOIS.

THE MAYOR of Moline has appointed W. A. MacBeth, a civilian, as a director of the hospital board to succeed Dr. A. H. Arp.

C. A. LUNDGREN, a magnetic healer, of Moline, was fined $100 and costs on December 21, for practicing medicine without a license. He was committed to jail on his refusal to pay his fine.

EVANSTON HOSPITAL is to be improved by the erection of the new Herman D. Cable memorial building, a three-story isolation, a boiler-house and numerous improvements to the present buildings, at an expense of nearly $50,000.

Chicago.

THE ISOLATION HOSPITAL received two smallpox patients on December 29, neither of whom had been vaccinated.

THE EXECUTORS of the will of the late George M. Pullman have paid Mary Thompson Hospital $10,000; St. Luke's Hospital $20,000, and Presbyterian Hospital, $10,000.

ST. LUKE'S HOSPITAL and two of its attending staff have been sued for $5000 damages because a boy treated at the institution and in the service of the two gentlemen, died of tetanus twelve days after a gunshot wound of the hand.

FOR THE WEEK ended December 22, the mortality of the city was at an annual rate of 14.73 per 1000. An unusual proportion of the 480 deaths occurred in those over 60 years of age—105 or nearly 22 per cent. Pneumonia caused more than 20 per cent. of the deaths.

BY AN AGREEMENT filed December 20, Thomas J. Kent and wife turn over to Wesley Hospital $25,000 to be used in constructing the hospital building, *contingent* on the payment of a 6 per cent. annuity to the donors, upon whose decease the gift is made absolute to the hospital.

THE FUNERAL SERVICES of Dr. Ephraim Ingals were held at his residence, December 20. Drs. N. S. Davis, Sr., Daniel R. Brower, Walter Haines, F. C. Hotz, Arthur D. Bevan, John Bartlett and J. Nevins Hyde were among the honorary pallbearers, and Drs. J. M. Dodson, J. E. Rhodes and J. Clarence Webster were the physicians among the active pallbearers.

INDIANA.

Dr. Robert C. Rogers, Bloomington, has been appointed acting assistant-surgeon in the army, and has been assigned to duty in the Philippines.

The representative from Daviess county in the state legislature is to introduce a bill providing that only physicians shall be eligible for coroner.

Dr. William N. Wishard, Indianapolis, has been appointed a member of the State Board of Health, vice Dr. P. Henry Jameson, Jr., Indianapolis, resigned.

The contract for the hospital for the incurable insane, which is to be erected in the grounds of the Central Hospital for the Insane, has been awarded, the contract price being $86,728.

Smallpox continues to increase in the state. Dr. James N. Hurty, secretary of the State Board of Health, has received reports of 100 new cases during December. The total number of cases reported since November 1, is 250, and of these 60 occurred in Allen county.

The State Board of Health has considered three points of medical legislation which it is proposed to lay before the general assembly at its coming session: 1, examination of all applicants for license to practice medicine; 2, that county clerks shall keep on file as a matter of record in their offices the certificates which the State Medical Board send to them, on which they issue license to medical practitioners, and 3, the enactment of a law defining the phrase "practice of medicine."

Compulsory treatment of liquor and drug habitués is the object of a bill to be introduced at the coming session of the legislature. The bill provides that any habitual drunkard who is a public charge or likely to become a public charge may, on application to the county judge, either in person or by friend or near kin, making oath to the facts in the case, be sent to an institution in which inebriates are cured. The expense, not to exceed $100, is to be paid by the county of which the beneficiary is a resident. Provision is made for the repayment of the money so expended, by the one benefited giving his note to the county commissioners and paying it as a whole or by installments.

IOWA.

Dr. Levi Loar, Selma, was found guilty on December 14 of performing a criminal operation on a young girl and sentence was deferred.

The Methodist State Hospital, Des Moines, which has been obtained by remodeling the Callanan college, is almost ready for opening.

Agatha Hospital, Clinton, was dedicated December 17. The building is 57x84 feet, three stories in height, and was erected at a cost of about $20,000.

The Iowa College of Physicians and Surgeons, which has been conducted for several years as an auxiliary school to Drake University, Des Moines, has been merged with the university.

The Supreme Court of the state has rendered a decision in the case of the State vs. W. M. Bair, which holds that the law requiring itinerant physicians to secure a license from the state board of medical examiners is constitutional.

The State Board of Medical Examiners met at Des Moines, December 18, and refused to issue a certificate to an osteopath, a graduate of the Still College of Osteopathy, Des Moines. The board has also declined to grant licenses to practice to graduates of schools of the same character at Quincy, Ill., and Kirksville, Mo.

KANSAS.

The physicians of Leavenworth met on December 4 and paid a last tribute to the memory of the late Dr. Jesse W. Brock.

The Hutchinson Board of Health has organized with Dr. Attila M. Hutchinson, chairman, and Dr. Cornelius A. Mann, secretary.

The main building of Stormont Hospital, Topeka, was burned, December 20, with a loss of $10,000. The eight patients who were in the hospital were removed in safety to the Santa Fe Hospital.

Since December physicians in Topeka who have not registered at the city physician's office in compliance with the city ordinance, are liable to a fine of $25. At last report 49 had failed to register.

LOUISIANA.

Dr. Ulysses G. Talley, New Orleans, was fined $25, December 11, for delaying to notify the board of health of a case of smallpox for two days.

Dr. William J. Emmer has been elected president of the reorganized New Iberia board of health, the other medical member being Dr. Alfred Duperier.

It is proposed by the New Orleans Health Department to introduce the Bertillon system of classification of causes of death with the opening of the new year.

The health department of New Orleans asked the city council for $31,000 to carry on its work, but the council cut down the estimate $26,000. The officers say that they will be compelled to discharge the whole sanitary force on January 1 for lack of funds to pay salaries.

The Senses Hospital, New Orleans, elected the following medical staff on December 12: Drs. Ernest E. A. Robin, Richard W. Salter and Timothy A. Duggan assistants in the eye department; Drs. Ambrose B. Gaudet, and H. J. Dupuy, assistant surgeons in the ear, nose and throat departments; Dr. Lieven De Poorter, resident surgeon for one year; Dr. Isadore Dyer, consulting dermatologist, and Dr. Gordon King, surgeon of the ear, nose and throat department.

MAINE.

Lowell Emergency Hospital has been incorporated at Kittery, capital stock not stated, to maintain an emergency hospital and dispensary.

The Sagadahoe Emergency Hospital, Bath, has recently been opened by Dr. Edwin M. Fuller. It contains all necessary equipment for the treatment of emergencies.

The Maine Eye and Ear Infirmary held its annual meeting at Portland, November 26. Dr. Eugene E. Holt, executive surgeon of the institution, reported that 1396 patients had been treated during the fiscal year: 749 in the eye department, 258 in the ear department, and 248 in adjunct clinics.

Dover has now 14 cases of scarlet fever, making in all about 40 cases since the end of September. All except two of the schools have been closed, and the Board of Health has now requested parents to keep their children confined to their own premises for a few weeks, to prevent the spread of the disease.

MARYLAND.

The one hundred and third annual report of the Maryland Hospital for the Insane at Spring Grove, Catonsville, shows that there were 626 patients in the institution during the year and 510 at its close. The superintendent recommends the erection of an industrial building for the female inmates.

Baltimore.

The health commissioner has taken steps for the sale of the old quarantine property, the proceeds from which are to be devoted to the establishment of a hospital for infectious diseases.

A fire took place in the library and laboratory of Dr. Howard A. Kelly on December 16, which damaged books and furniture to the extent of $2000, and the building to the extent of $600.

Baltimore University Hospital was damaged by fire to the extent of $1000 or $1500 by fire shortly after midnight December 18. The patients were all rescued. The books, etc., in the faculty room were destroyed, but the prompt response of the fire department saved the building from entire destruction.

Dr. Walter Wicks has resigned as assistant resident physician at the University of Maryland Lying-in Hospital. Dr. A. C. Hoyt, third assistant on the surgical staff of the Maryland University Hospital, will succeed him and Dr. A. J. Edwards, of Winston, N. C., one of the assistant resident physicians at the hospital last year, will fill Dr. Hoyt's place.

The number of cases of diphtheria reported for December was only about half that of last December. The decrease is attributed by Dr. Bosley to the enforcement of the new law of the department prohibiting public funerals of persons dying from the disease, and the quarantining of infected houses. The people accept the new rule kindly and coöperate with the department in its execution.

MASSACHUSETTS.

Drs. Edward C. Frost and Thomas H. McCarthy have been appointed members of the staff of the Brockton Hospital.

Dr. Joseph B. Howland has succeeded Dr. Archibald J. Ranney as assistant superintendent and physician at the State Almshouse Hospital, Tewkesbury.

The trustees of the Dickinson Hospital, Northampton, have received a donation of from $15,000 to $20,000 for the purpose of building an annex to the hospital 50x30 feet in extent.

The Waltham Board of Health has issued notices to all physicians in its jurisdiction to report at once all cases of typhoid fever. The board has made an investigation to ascertain the source of the infection which has caused so many cases of the disease and has traced it to a farm on the outskirts of the city which supplied milk to many of the families where the disease existed.

MICHIGAN.

Dr. James E. Mead, Detroit, has been appointed acting assistant-surgeon in the army.

License to practice was refused to about forty applicants in Wayne County by the State Board of Registration.

Dr. James H. Kellogg, Battle Creek, was stabbed, but not seriously wounded, by an insane patient, December 22.

A new sanatorium is planned on Manitou Beach, Devil's Lake, twenty miles south of Jackson, by a syndicate of physicians.

A "diplomate" of the notorious Independent Medical College was arrested at Grand Rapids, December 17, on the charge of practicing medicine without having legally registered. It is likely that this will be made a test case.

A well-organized effort is to be made by the enemies of the new medical registration law to attack it at the regular session of the state legislature, and, if possible, to have it wiped off the statute books, or so changed by amendment that much of its present strength will be taken away.

MINNESOTA.

Despite the resolution of the Duluth Board of Education that unvaccinated children be admitted to the public schools, Health Commissioner Robinson, backed by the recent decision of the county court, stands firm and will prevent the attendance of these children at school.

About eight hundred houses at Winona have been under quarantine for smallpox during the past two months, but now from twenty to thirty patients a day are being released and there are not more than 400 cases now on hand. The disease is in a very mild form and only few deaths have occurred.

The state commission appointed to investigate and report on the condition of the state asylums and hospitals for the insane is heartily in favor of the plan now being pursued in the new institutions at Anoka and Hastings. In its report special mention is made of the benefits received by patients in the smaller institutions.

MISSOURI.

Dr. Clarence Loeb, St. Louis, interne at the City Hospital, has resigned and will be associated in practice with Dr. Carl Barck.

Kansas City is to have a new pest-house 200 feet long by 20 feet wide, capable of accommodating 80 patients, and erected at a cost of $2300. On December 14, 17 patients were sent to the isolation hospital.

St. Luke's Hospital, St. Louis, will soon have a new building on Dedmar avenue, where a site has been purchased by the board of trustees. The amount—$100,000—required for the erection of the building has almost all been subscribed.

Dr. George O. Coffin, city physician of Kansas City, is enforcing rigidly the compulsory vaccination ordinance for school-children and has asked the superintendent of public schools to furnish the board of health with lists of all school children with vaccination or no vaccination noted opposite each name.

Dr. L. C. McElwee, secretary of the State Board of Health, has asked for a special appropriation of $25,000 to assist in stamping out variola, which has appeared in 96 out of 114 counties of Missouri. If allowed, vigorous quarantine measures will be established, which will certainly be necessary to prevent the spread of the disease.

NEW JERSEY.

Dr. Thomas N. Gray has been appointed city physician of East Orange, to fill the unexpired term of Dr. Winthrop D. Mitchell.

On Christmas Day, Thomas H. Vinter, executor of the estate of the late Benjamin D. Maxham, presented the New New Jersey Training School for Feeble-Minded Children at Vineland with $100,000.

Owing to smallpox in Jersey City, the president of the State Board of Health issued an order that precautions be taken against its spread. At Lorillard's tobacco factory about 4000 girls were ordered vaccinated.

According to the last report of the Board of Children's Guardians of the State, made to the Governor, the results prove that it has not been hard to get children out of the almshouses and place them in country homes, some free of charge, and others at a rate of $1.50 per week. Last year the legislature appropriated $2000 for this purpose, but this sum has been found insufficient. An appropriation of $6000 will be asked for.

NEW YORK.

The sixteenth annual report of Flushing Hospital shows a large increase in donations and subscriptions, but a larger increase in expenses. The board of estimate and apportionment gave the hospital $7500 in 1899.

Dr. William P. Spratling, medical superintendent of the Craig Colony at Sonyea, gave a dinner at the colony to the members of the Livingston County Board of Supervisors and other invited guests, at which the work of the institution was reviewed by the members of the board of directors, and suggestions made as to opportunities for improvement.

Buffalo.

The new morgue building, when finished, will be one of the most modern and complete of the kind in the United States.

The University of Pennsylvania exhibit, which was one of the most complete in the Paris Exposition education department, will be brought to Buffalo for the Pan-American Exposition.

The board of supervisors has approved the following appropriations for 1901: Buffalo Eye and Ear Infirmary, $2200; Charity Eye and Ear Infirmary, $1800, and German Hospital Dispensary, $1500.

The German Hospital bazaar closed December 16. About $5000 was realized. The hospital will now receive its proper furnishings for wards and private rooms and will be ready for the reception of patients by February 1.

The plans for a cancer hospital in connection with the Buffalo General Hospital have been filed with the bureau of buildings. They provide for a three-story fire-proof building, which will be used as an annex of the Buffalo General Hospital and will be erected near that institution.

Many of the physicians of Erie County, who have long been members of the New York State Medical Association, now propose to organize a county association in affiliation with it and in accordance with its charter and by-laws. A meeting of organization was held on December 20.

New York City.

During the last week of 1900, 23,782 persons were vaccinated in the city, 4500 of whom were inmates of lodging houses.

The board of health decided, December 19, to use the Bertillon system in classifying the causes of death in the Bureau of Records after January 1.

The nurses in charge of the Bellevue Hospital alcoholic ward, who were charged with brutality toward patients, have been suspended pending further investigation and have been held by the grand jury to answer to the charge of manslaughter.

PENNSYLVANIA.

Dr. M. C. Warren has resigned as resident physician at the Reading Hospital and has been succeeded by Dr. Thomas C. Buchanan, Honeybrook.

The committee on public buildings and grounds has reported favorably on the Dalzell bill, appropriating $91,000 for a United States marine-hospital at Pittsburg.

The osteopath at Beaver Falls, "Dr." E. E. Pierce, charged with practicing medicine and surgery without a license, was found guilty and recommended by the jury to the mercy of the court.

Cases of smallpox are still being found in Pittsburg in districts supposed to be free from the disease. On December 25 a case was discovered and the patient taken to the Municipal Hospital. Several other inmates of the room were also removed and taken to the hospital to prevent the spread of the disease. On December 23 an unknown man was found in one of the parks and was taken to the Allegheny General Hospital, where his condition was diagnosed smallpox. He was at once removed to the Municipal Hospital.

Philadelphia.

On December 24, Coroner Dugan held inquests in 24 cases. Verdicts were reached in 21 instances, and 3 have been continued.

The city councils have made the following appropriations for the year 1901: Bureau of health, $207,080; bureau of charities, $576,678, and coroner, $30,300.

By the will of John Betz, recently deceased, $2000 has been given the German Hospital. This hospital has also received $1000 from the Baldwin Locomotive Works.

VIRGINIA.

The Richmond Academy of Medicine and Surgery has adopted appropriate resolutions on the death of the late Dr. Frank S. Harker.

A FIRE in the Virginia Hospital, Richmond, December 10, caused great excitement and alarm, but fortunately only slight damage and no loss of life.

DR. ALBERT S. PRIDDY, Charlottesville, the nominee of the State Medical Society, has been appointed a member of the medical examining board of the state-at-large.

DURING THE YEAR 435 patients were under treatment, on the average, at the Central Hospital for the Insane. The new admissions numbered 192, and of these two-thirds were discharged cured. The board of directors will ask the legislature to make an appropriation sufficient to erect three new female wards.

GENERAL.

ON DECEMBER 11 three Franciscan nuns arrived in Honolulu from New York State. They go to Molokai to work among the lepers.

F. R. DAY, M.D., for many years a member of the Honolulu Board of Health and port physician, resigned his positions in November, and sailed a few days ago for California, on his way to Berlin, where he will take up special medical studies for two years.

LEPROSY IN THE PHILIPPINE ISLANDS.

An appended report to General MacArthur's review of the civil affairs of the Philippines for the last fiscal year gives some rather startling facts regarding the introduction and prevalence of leprosy in the islands. According to the estimates of the Franciscan fathers, says Major Guy L. Edie, the writer of the report, there are no less than 30,000 lepers in the archipelago, the major portion of these being in the Viscayas. Leprosy was introduced in 1633, when the Emperor of Japan sent a ship with 150 lepers to the Philippines to be cared for by the catholic priests. Thus the seed was planted, and, as no practical methods ever were adopted to eradicate the disease or prevent its spread, it has taken firm root. A house-to-house inspection begun last January found more than 100 lepers concealed in dwellings. These were sent to San Lazaro hospital in Manila, but many others escaped into the surrounding country. A commission is now engaged in the work of selecting a suitable island or islands for the purpose of isolating all the lepers in the archipelago.

WAR ON MOSQUITOES.

The United States government has formally recognized the responsibility of the mosquito for the transmission of yellow fever and malarial diseases. This fact is indicated by the issuance of a general order by Major-General Wood at Havana, directed to his post commanders reciting that the chief surgeon of the Department of Cuba has reported that it is now well established that malarial, yellow fever, and filarial infection are transmitted by the bites of mosquitoes. The troops are therefore enjoined to observe carefully two precautions: 1, they are to use mosquito bars in all barracks, hospitals, and field service whenever practicable; they are to destroy the larvæ or young mosquitoes, by the use of petroleum on the waters where they breed. Permanent pools or puddles are to be filled up. To the others are to be applied one ounce of kerosene to each fifteen square feet of water twice a month, which will destroy not only the young, but the old mosquitoes. This does not injure drinking water if drawn from below and not dipped out. Protection is thus secured, according to the order, because the mosquito does not fly far; seeks shelter when the wind blows, and thus each community breeds its own mosquitoes.

ETHER VERSUS CHLOROFORM IN THE TROPICS.

In a report to the surgeon-general of the army on the operative work at the First Reserve Hospital, Manila, P. I., from Sept. 1, 1899, till Feb. 28, 1900, Major W. P. Kendall, surgeon, U. S. A., makes some interesting remarks on the anesthetics used. The cases included 49 of hernia, radical cure; 19 appendicitis; 15 amputations, including two of the hip-joint, one of which was successful; 35 of hemorrhoids; 13 varicoceles; 1 ligature of the external iliac, the femoral and the subclavian in its second part, all successful, and many other operations involving the use of a general anesthetic. "Regarding the choice of anesthetics," says Surgeon Kendall, "there was an apparent difference, not seen in the United States, between ether and chloroform. Whether this would disappear after a longer experience and some modified way of administration or not was not determined; but, as it was, we all grew to be afraid of chloroform, including those whose experience with it had been large, even to the exclusion almost of ether. Heart failures came on rapidly and with great severity, producing death in two chronic appendicitis cases before operation was begun. Besides these there were several cases of suspended animation, while with ether no trouble was observed. Our experience fully confirms that of those who claim that in hot countries the paralyzing effect of chloroform is greater than when used in colder climates, due, probably, to the lack of tone of the motor nervés.

DR. GEORGE M. GOULD AND THE PHILADELPHIA MEDICAL JOURNAL.

The following telegram was received after our note referring to the editorial change in the *Philadelphia Medical Journal* was in type:

PHILADELPHIA, Jan. 1, 1900.

Dr. George H. Simmons: I have just received the first official intimation that my services are no longer desired as editor of the *Philadelphia Medical Journal*, the discharge to take effect immediately. The following editorial, written from private information, was inserted in the issue of December 29, but was not allowed to appear. For considerations of courtesy to many subscribers, I would be pleased to have you publish this hurried word of goodbye to the profession. The extinguished editorial is as follows:

A Personal Word from the Editor.—Just as the last forms are going to press I learn that the present number of the *Philadelphia Medical Journal* will be the last—except as to the original article department of the next issue—for which I shall have editorial responsibility. I am unable to set forth the reasons why the board of trustees no longer wish my services as editor. I am in complete ignorance what such reasons may be. I have heard of no criticism upon their part of my conduct of the journal, and my communication handed to the board in session on December 8, expressing my desire to be retained as editor, has not been answered. To the thousands of friends, to all subscribers who may read these lines, I can only here express my most profound regret at the sudden separation. In the endeavor to aid in establishing a great independent medical journal, utterly free from publishers' influence, from commercial bias and from what is, if possible, still worse, an unprofessional spirit within the profession, I have given my labor and my life, all too freely. What mistakes I may have made I trust may be excused in the belief that they were due to a sincere desire to devote every line of the reading columns to the cause of professional truth and honor.—GEORGE M. GOULD.

FOREIGN.

TYPHOID FEVER occurred, up to September 28, in 15,655 British soldiers in South Africa, with a mortality of 3642.

A NATIONAL association of the medical press has recently been organized in Denmark, Norway, Sweden and Russia in response to the efforts of Dr. R. Blondel, of the French association, who visited the chief cities in these countries.

THE FACULTY of medicine of the University of Edinburgh, according to the *British Medical Journal*, has formally expressed its disapproval of the publication of laudatory certificates from its graduates, in trade advertisements.

THE BUBONIC plague has increased in death-rate in India to the extent of about 50 per cent. during the last month. On the other hand, the famine ceases to be a noticeable factor in mortality; at present only 500,000 require assistance.

THE GERMAN imperial bill lengthening medical study to at least 5 years, meets with the approval of the profession. Berlin has one physician to every 798 of the population, Breslau one to every 775, Halle one to every 735, and Koenigsberg one for every 681.

THE PHYSICIANS who attended the Czar in his illness have just received their rewards. Dr. Hirsch, the famous surgeon, has been given the Order of Alexander-Newski, established by Catherine the Great. Prof. Popoff has been made the Czar's body physician, and Dr. Tichokonoff honorary medical adviser.

THE BRITISH ambassador at Pekin, Sir Claude MacDonald, in his dispatches, refers to the valuable services of Drs. Morrison, Poole and Velde during the late memorable siege. The two latter were in charge of the International Hospital, where 166 cases were treated, 20 of which suffered from illness and the rest from wounds.

THE ROMAN correspondent of the *Lancet* states that a statue of Aesculapius has recently been found in the Roman Forum. The head and part of the right arm are missing. The god is represented with a *volumen* of parchment or paper in the left hand, leaning on a staff around which is coiled a serpent, the symbol of renovation. It was found near the Well of Juturna, reputed for the salubrity of its water.

PROFESSOR CELLI estimates in his new work "La Malaria," an annual mortality in Italy of 15,000 due to malaria, and states that 5,000,000 acres of good soil remains uncultivated. As member of the Italian parliament, he proposes to make it obligatory on landowners and employers to provide every possible agent against the scourge. It is likewise proposed that the government supply the sufferers with pure quinin at a trifle above cost price.

THE DEATH of Professor Podrèze of Charkow is announced, in consequence of a fall from his horse. The eminent Russian surgeon was in his forty-ninth year, and by his will his property, including his private clinic, is bequeathed to the Charkow university to found a clinic for urogenital diseases. Both the physicians attached to the Belgian ambulance dispatched to the Transvaal have died in the last few months.

THE *Wiener Med. Woch.* of December 1 publishes a line from Prof. Stofèlla to the effect that he can not subscribe in all respects to the communication purporting to be from his polyclinic in the two preceding numbers of the *Wochenschrift* on the "Medicinal Treatment of Tuberculosis," by Adolf Hoff, reviewed in THE JOURNAL of Dec. 22, p. 1635. He states that the results of his observation and experience of the treatment described have not always corroborated those of Dr. Hoff.

SANITARY PRECAUTIONS ADOPTED AT OSAKA, JAPAN.

In a letter of Dec. 4, 1900, received by the surgeon-general of the Marine-Hospital Service from the acting asst.-surgeon on duty in the office of the United States consul-general at Yokohama, it is stated that, from June 19 to November 5, 1900, 176,818 rats were destroyed in Osaka. A conference of sanitarians and quarantine officers was at that time sitting in Tokyo, under the order of the Home Department, with the object, if possible, of devising some method of combating the plague, more effective than that hitherto employed.

CANADA.

THE Montreal Health Department has created a department for the inspection of food, with Dr. J. J. McCarrey as superintendent.

DR. OSCAR F. MERCIER has recently been appointed head surgeon of the Notre Dame Hospital, Montreal. He will also be professor of the surgical clinic.

THE Hygienic Committee of Montreal has decided that hereafter three doctors be appointed to sit with the committee. For this they will receive compensation at the rate of $5 per diem.

DR. F. J. SHEPHERD, of Montreal, has just returned from Havana, where he accompanied Sir William Van Horne. He has been elected a vice-president of the Pan-American Medical Congress and president of the section on pathology. He will attend the sessions in February next.

MONTREAL GENERAL HOSPITAL.

This hospital is still in hot water financially. Fifteen thousand dollars is needed as an augmentation fund each year to enable the trustees to carry on the work of the institution. The capacity of this hospital has doubled since 1885. In that year the revenue was $39,308 and the expenditure $40,910. In 1900, the revenue amounted to $67,421, while the expenditure was $81,570, showing a deficit of $14,149. The increase in public subscriptions in that time has only been 25 per cent., but the number of out-door patients has increased from 13,000 in 1885 to 37,000 in the present year.

HOSPITAL FOR SICK CHILDREN, TORONTO.

The twenty-fifth annual report of this institution has just been issued. It covers the work done for the year ending Sept. 30, 1900. The daily average of patients for the previous year was 101½, and for the present year 111½. During the twenty-five years of the hospital's existence over 40,000 children have been treated. The total income for 1900 was $56,116, and the expenditure $36,274. The assets of the hospital now total $215,180, and a nominal liability of $3000 or $4000 is expected to be wiped out by the end of the year. In connection with this institution is the Lakeside Home for Little Children on Toronto Island, which is the largest sanitarium for children in the world.

PHYSICIANS' AND SURGEONS' SUPPLY COMPANY.

A synopsis of a plan for securing better and cheaper drugs for medical practitioners was given in the columns of THE JOURNAL some little time ago, as proposed at a meeting of the Huron Medical Association by Dr. J. R. Shaw, of Clinton, Ont. A charter has been applied for and several members of the profession in Western Ontario and also some few in Toronto are interesting themselves in forming a company to be known as the Physicians' and Surgeons' Supply Company(Limited). The success of the enterprise seems assured from the amount of stock already subscribed. The company is not meant as a combine in any way, but the druggists will be no longer compelled to keep brands of drugs to suit every doctor's whim. A meeting will shortly be held in Toronto for completing organization. Dr. Gunn, of Clinton, is the provisional president.

LONDON LETTER.

THE "EPIDEMIC" OF ARSENICAL POISONING FROM BEER-DRINKING.

The epidemic of arsenical poisoning in Manchester and the surrounding districts, which I have described in my last letter, has caused a wide-spread scare among beer-drinkers throughout England. In London the publicans are posting on their windows notices that they guarantee their beer free from arsenic. Everywhere analyses have been made of the beer sold for consumption, but outside the districts mentioned it has been found uncontaminated. In Manchester alone about 2000 people have been under medical treatment for arsenical peripheral neuritis, to say nothing of milder cases which did not come under observation. The medical officer of health of Manchester, in his report on the epidemic, states that examination of the glucose used in the 20 Manchester breweries revealed arsenic only in that of 5. This glucose all emanated from a single firm and contained arsenic in considerable amount. A number of deaths are alleged to have taken place from arsenical poisoning, but definite proof is lacking in these cases that arsenic was the cause of the fatal result. However, the statistics show that the deaths from peripheral neuritis in Manchester have nearly doubled in 1900. In the first 48 weeks of the years 1897, 1898, 1899, and 1900 the deaths from peripheral neuritis were 11, 17, 18 and 39 respectively. Persons of all ages and both sexes were affected. The youngest patient who suffered from arsenical poisoning from beer-drinking was a little girl of 2, the daughter of a publican who was petted by the customers and given small quantities of beer to drink. Two cases have been recorded in which infants at the breast were poisoned by their mother's milk and recovered when cow's milk was substituted. In one, a woman aged 32, took stout after confinement. After five weeks she felt numbness of the fingers and "jumping" in the feet; her eyes began to smart and her throat became sore. At the same time the child began to vomit after every nursing. It became emaciated and snuffled. Its feet were slightly erythematous. A number of beer-sellers in Manchester are to be prosecuted for selling impure liquor. At Salford, a town near Manchester, it is stated that 6 deaths from drinking arsenical beer have occurred. At Liverpool, a number of cases of arsenical neuritis have been observed, but nothing of the nature of an "epidemic." It is interesting that in one case arsenic was found in the urine. At Chester 8 samples of beer from 7 breweries were examined, and 4 were found to contain arsenic. A number of cases of peripheral neuritis have occurred. Upward of 500 barrels of beer have been destroyed.

THE PARASITOLOGY, ETIOLOGY AND PREVENTION OF MALARIA.

At the Royal Medical and Chirurgical Society Dr. Manson gave a résumé of recent advances on this subject. In 1896-97 the cycle of the malarial parasite to the human body was studied, but the cycle external to the body was not studied. How it was introduced was not known, but since the organism was a blood parasite, some blood-sucking animal was suspected as the means of infection, and there were epidemiological and geographical reasons which pointed to the mosquito. Surgeon-Major Ross, by two or three years indomitable perseverance, conclusively proved the truth of the mosquito theory. He first studied the evolution of the coccidium Schübergii in bird malaria and found there were an endogenous and an exogenous phase. Then he found that the parasite of estivo-autumnal fever was strictly analogous. In the blood of man its evolution was asexual, in the mosquito bisexual. As to the various kinds of mosquito concerned in the conveyance of infection hitherto only anopheles had been implicated in malarial infection, and of this there were 46 known species. In 7 of these the mosquito had been found. Recent investigations have shown that children are specially susceptible to malaria; as many as 70 or 80 per cent. of native children under one year of age contract it. The proportion of infected becomes gradually smaller as age advances until 10 or 12 years is reached. An immunity of some kind seemed to be obtained by the native population. Practically all deaths from malaria occurred in children. The etiology of blackwater fever was still undiscovered. The suggestions that it might be due to a special type of malaria parasite or a parasite the virulence of which was increased by being transmitted through a particular species of mosquito, or a disease sui generis, were all tenable, but they lacked confirmation. As to prophylaxis, four means were available—to avoid the natives, to take quinin, to destroy mosquitoes, and to protect oneself against them. These measures were efficient but not always applicable. Complete protection was perhaps impracticable, but relative protection was valuable and was always possible.

THE DIAGNOSIS OF TREATMENT OF THORACIC ANEURYSM.

At the Medical Society of London Dr. Kingston-Fowler said that the diastolic thud was a sign of the greatest value since it was present in no other condition. Tracheal tugging also indicated aortic aneurysm. The only fallacy was that a new growth almost surrounding the aorta and attached to the trachea might communicate movement to it. The treatment consisted of several factors. Rest and iodid were very efficacious in the relief of pain. If no improvement took place he then added a modified Tufnell diet. Seven ounces of solids and eight of fluids daily were the quantities he had adopted. Lanceraux' method of treatment by gelatin injections he had seen carried out in 3 cases. His experience was not favorable. One of the patients had probably been benefited. Where spasm of the laryngeal muscles existed inhalations of oxygen and the injection of morphia were useful. The prognosis of aneurysm he believed was better than was generally thought. He had known several patients to live for years—one for 13 years, another for 6, and another for 9.

Correspondence.

Origin of Leprosy in Hawaii.

Koloa, Kauai, H. I., Dec. 15., 1900.

To the Editor:—In your issue of November 17 last you say editorially in regard to the origin of leprosy in Hawaii, its protection by the chiefs, etc.:

"The missionary physicians soon learned to recognize it, and one of them, Dr. Dwight Baldwin, it is said, made a report of it, stating the facts of its origin. . . . So long as the Hawaiian monarchy existed, segregation of lepers, though legally demanded, was very imperfectly carried out, owing, it is said, to the interference in high places. . . . The isolation law is an unpopular one with the natives. . . . These data were obtained from the Honolulu *Commercial Advertiser*, whose authority for the main facts is the Rev. Sereno Bishop. . . . *We have not seen this bit of medical history narrated elsewhere.*"

In my article on leprosy, which appeared in the *New York Medical Record* of Jan. 27, 1900, and which was republished in book form several months ago, I said:

"The first leprous man in Hawaii that came to the notice of the general public, was a native man named Naea, who died in 1852, after having been a leper for ten years. His case was reported by Dr. D. D. Baldwin of Lahaina, who, in 1863, discovered that there were 50 lepers in his church. He was a physician as well as a minister. . . . The same year Dr. Hillebrandt, surgeon to the Queen's Hospital, wrote: 'I wish to bring to the public's notice a subject of great importance. . . . It is genuine oriental leprosy. Repeated investigations leave but little doubt in my mind about the contagious character of the disease.' . . . It was called by the natives 'mai pake,' or Chinese disease."

The name "mai alii," not "ma'i alli," as you have it—was never so current as "mai pake," which is the common name for leprosy.

"In 1864 the board of health appointed Mr. Jourdan to take a 'leper census,' and report the same. . . . In January, 1865, the King signed an act providing that certain lands be 'set apart' for 'the isolation and segregation of lepers'; that the board of health or its agents 'be authorized and empowered to cause to be confined all lepers who shall be deemed capable of spreading the disease of leprosy.' . . . With all his talk, Mr. Gibson delayed the good work of segregation, and during the time that he was president of the board of health very little effective work was done. When, later on, Dr. Emerson and others took up the health matters of the country, it was with added difficulty. . . . It was the sad fate of Dr. J. K. Smith to die by the hand of a man whose wife the doctor had ordered to Molokai."

In his official report for 1884, W. M. Gibson, as president of the board of health, says: "But it is difficult to indulge in any reflection on the action of my predecessors because the law requiring segregation has not been carried out with rigor. For what does this law require? That men, women and children shall be torn from their homes [here is a recital of several pathetic cases]. These are some of the experiences and consequences of the law. . . . There should be no alarm in consequence of the temporary presence in the street of a leper; or on account of any ordinary intercourse with sufferers from this disease. . . . According to invariable experience in the observation of this disease in this country and elsewhere, such a sufferer may pass the healthy in the street or frequent the same room with them in the ordinary intercourse of life."

This was a shameless bid for the favor of Kalakaua and his native population. Following the report of Gibson is that of Dr. N. B. Emerson, then—1884—superintendent of the leper settlement, in which he says: "I can not refrain from remarking with great regret the comparatively small number of lepers that have been brought to this settlement from without during the past year, when one considers the great number still at large in the community. I gravely apprehend that this may prove a matter of serious regret to the Hawaiian nation in the future."

In a contribution to the *Philadelphia Medical Journal*, June 2, 1900, I said: "With 4000 lepers scattered over the group, the Hawaiian government began to segregate at first in an inefficient way, retarded often by ignorant and designing officers. . . . In the 34 years during which Hawaii has practiced segregation *the law has been really enforced in the last 14 only.*"

In respect to the first case of leprosy in Hawaii, accounts differ. Sereno Bishop thinks that Kakauonohi, a Hawaii chief, contracted leprosy in China—to which country Hawaiian ships frequently went with sandalwood—and introduced the disease among his people. In a personal interview with ex-Queen Lilioukalani she said she remembered seeing the first leper on Oahu, and that he was a chief who had been to China.

On the other hand, the government "Biennial Report," issued in 1888, says: "Leprosy was first made out to exist in this country about the year 1840, in the person of one Naea, a messenger of the chief, who died in 1852. His case was reported by Rev. D. D. Baldwin, M.D., of Lahaina, in a communication to the minister of the interior, dated May 26, 1864."

E. S. Goodhue, M.D.

Foreign Bodies in the Ear.

Burlington, Ia., Dec. 30, 1900.

To the Editor: I hope that I shall not be accused of trying to make a mountain out of a molehill, but I think that somebody should at least say that your other correspondent on this subject, in The Journal of December 22, page 1643, is preaching just as pernicious a doctrine as that he assumes to condemn.

Personally speaking, after an experience of more than twenty years, with a fairly numerous clientèle, I am unable to recall a single instance where serious permanent damage resulted from retention of foreign bodies in the ear. Several years ago I removed a small piece of slate pencil—case was reported then —which my patient maintained she had poked into the canal when she was a child twenty years before. So far as I could see, it might have safely remained there another twenty years, imbedded as it was in cerumen. Insects whole and in pieces I have extracted after months and years of lodgment.

On the other hand, and this I think is a common experience among aurists, or the books would not so universally speak of it, I have seen no little damage done by ill-advised and ill-devised attempts at extraction—particularly where instrumental delivery was the means adopted.

In a paper which I prepared many years ago for the annual meeting of our State Medical Society I formulated a rule, which I still hold as covering the situation. It was in this wise:

Be sure that the foreign body is in the ear. Then remember that if it is of such consistency and size that it will offer resistance to such a stream of water as you can introduce with a syringe, then the stream of warm water from a syringe, with the nozzle at the highest margin of the meatus, will bring it out. But the foreign body may be such that it offers no resistance—insects like mosquitos whose diaphanous wings will bend before the stream and flatten out against the walls—or the stream of water can not be thrown to the bottom of the canal on account of the swelling of the surrounding tissues or the swelling of the foreign body itself in the event of its being one of the cereals. Then remember that you must have either an experienced technique with ear instruments or you must confine yourself to an attempt to reduce the swelling only.

Personally speaking, again, I do not want any foreign bodies in my ear; but I will take my chances with the ordinary kind rather than the bent probe—or forceps—in the hands of one whose technique I do not thoroughly know. Truly yours,

H. B. Young, M.D.

Marriages.

Luther C. Fischer, M.D., to Miss Lucy Hart, both of Atlanta, Ga., December 12.

Harry W. Lyman, M.D., to Miss Sarah Long, both of St. Louis, Mo., December 12.

Richard Finlay, M.D., to Miss Luella Duer, both of Centreville, S. D., November 29.

Marshall Clinton, M.D., to Miss Alethe Evans, both of Buffalo, N. Y., December 12.

Frank M. Thigpin, M.D., to Miss Stella White, both of Pensacola, Fla., December 12.

Edward E. Maxey, M.D., to Miss Edna Horn, both of Caldwell, Idaho, December 19.

S. Howell Gardner, M.D., Sharpsburg, Md., to Miss Harriett Christian, of Mount Carroll, Ill.

Van E. McFarland, M.D., to Miss Alice Townsend, both of Eagle Pass, Texas, December 12.

G. Hudson Makuen, M.D., Philadelphia, to Mrs. Nancy Dyer, of Chester, Pa., December 20.

William K. Murray, M.D., Chicago, to Miss Gertrude Nelan of Pittsburg, Pa., December 20.

Frederick C. Peterson, M.D., to Miss Sarah M. Bradford, both of Watertown, N. Y., December 31.

William L. Haynes, M.D., Memphis, Tenn., to Miss Clarice Hancock, of Calhoun, Ky., December 18.

Charles P. Martin, M.D., Woodstock, Ala., to Miss Willie Reid, of Russellville, Ala., December 12.

John M. Blair, M.D., Monroe, N. C., to Miss Hannah J. Saunders, of Hagood, S. C., December 27.

Hiram D. Peterson, M.D., Kelley's Island, Ohio, to Miss Mattie E. Cleveland, of Huron, Ohio, December 12.

Maurice M. Scheuer, M.D., Valley Junction, Iowa, to Miss Dora Anderson, of Des Moines, Iowa, December 11.

Deaths and Obituaries.

John J. Garver, M.D., Medical College of Ohio, Cincinnati, 1877, a member of The American Medical Association, Indiana State and Marion County Medical Societies, at his home in Indianapolis, December 13, after an illness of thirteen weeks, aged 55. The Marion County Medical Society has appointed a committee to prepare resolutions on the death of Dr. Garver.

Peter F. Curley, M.D., Albany Medical College, Albany, N. Y., 1883, member of the State Board of Health, State Board of Medical Examiners, and of the local, state and American Medical Association, at his home, Newport, R. I., December 13, from Bright's disease, aged 39.

Aldea A. Glasscock, M.D., Missouri Medical College, St. Louis, 1868, at his home in Ventura, Cal., from cancer of the tongue, after an illness of several months, December 11, aged 62.

Charles J. O'Hagan, M.D., New York Medical College, 1856, a member of the American Medical Association, at his home in Greenville, N. C., from apoplexy, December 18, aged 80.

John Wheeler, M.D., Berkshire Medical College, Pittsfield, Mass., 1852, formerly president of the New Hampshire State Medical Society and a surgeon throughout the Civil War, at his home in Pittsfield, N. H., December 21, after a year's illness from paralysis, aged 72.

Theodore Giddings, M.D., College of Physicians and Surgeons, N. Y., 1868, from apoplexy, at his home in Housatonic, Mass., December 28. He was a member of the American Medical Association, and served in the legislatures of 1886 and 1888.

Richard A. Wise, M.D., Medical College of Virginia, Richmond, 1868, representative from the second district in the present Congress, from Bright's disease, December 21, at Williamsburg, Va., aged 57.

Randolph H. Hall, M.D., Rush Medical College, 1882, president of Illinois Medical College, and a member of the American Medical Association, at his home in Chicago, December 30, aged 56.

Ulysses H. Brown, M.D., a prominent oculist and a member of the New York State Medical Association and The American Medical Association, probably from accident, in New York City, December 28.

Daniel F. Collins, M.D., Bellevue Hospital Medical College, N. Y., 1873, formerly president of the Minnesota State Board of Medical Examiners, at St. Mary's Hospital, West Superior, Wis., December 22.

George H. Elliott, M.D., Denver Medical College, 1882, of New York City, a commissioner of lunacy in New York, at his father's house in Manchester, N. H., December 17, aged 56.

James C. Brownlee, M.D., Bellevue Hospital Medical College, 1880, at the German Hospital, Kansas City, Mo., from pneumonia, after an illness of three weeks, December 19.

Justus M. Townsend, M.D., Berkshire Medical College, 1880, at the German Hospital, Kansas City, Mo., from pneumonia, after an illness of three weeks, December 19.

George W. Greenleaf, M.D., Bowdoin Medical College, Brunswick, Me., 1894, surgeon of the Southern Pacific Railroad, at Yuma, Ariz., at Yuma, December 1, aged 30.

Charles D. Willis, M.D., University of Tennessee, Nashville, 1888, after a lingering illness, from consumption, at his home, Greenville, Tenn., December 13, aged 40.

R. A. Rogers, M.D., Cincinnati College of Medicine and Surgery, 1877, of Welton, Iowa, after an operation for appendicitis, at Davenport, Iowa, December 15.

William H. Jones, M.D., University of Pennsylvania, 1863, U. S. Navy, retired, at Bethlehem, Pa., after several years of illness, from diabetes, December 14, aged 60.

Charles E. Acree, M.D., Vanderbilt University, Nashville, 1892, at his home in Eddyville, Ky., December 23, from uremia, after a long illness, aged 50.

George W. L. Howland, M.D., University of Michigan, Ann Arbor, 1870, from injuries received in a runaway accident, at Flint, Mich., December 27.

Verner L. Chesley, M.D., Dartmouth Medical College, Hanover, N. H., 1899, at his home in West Swanzey, N. H., December 14, from pneumonia.

Alvin Duval, M.D., University of Louisville, 1878, at the home of his mother in Frankfort, Ky., after a long illness, December 15, aged 35.

Levi Oberlin, M.D., who had practiced medicine in Clinton, Ohio, for nearly half a century, at his home in that place, December 8, aged 73.

Andrew J. Smith, M.D., Northwestern University Medical School, 1871, at his home, Wabash, Ind., from apoplexy, December 22, aged 70.

Robert V. R. Montfort, M.D., Albany Medical College, Albany, N. Y., 1856, at his home in Newburg, N. Y., December 18, aged 65.

Mary E. Christy, M.D., Woman's Medical College, Philadelphia, 1894, at her home in New Castle, Pa., December 14, aged 31.

John E. Losee, M.D., Albany Medical College, Albany, N. Y., 1852, at his home in Upper Redhook, N. Y., December 22, aged 74.

Charles L. Gwyn, M.D., University of Maryland, 1860, at his home in Galveston, Tex., December 8, from septicemia, aged 62.

Dean M. Tyler, M.D., University of Michigan, Ann Arbor, 1859, at his home in Ann Arbor, December 11, after a long illness.

John Henry Fruitnight, M.D., Bellevue Hospital Medical College, New York, 1875, at his home in New York, December 18.

Elijah H. Grigg, M.D., Medical College of Virginia, Richmond, 1860, at Sheppards, Buckingham County, Va., December 20.

Frederick Osborn Lloyd, M.D., New York University, 1885, December 19, at Hamilton, N. Y., from consumption, aged 40.

William P. Gatlin, M.D., University of Louisville, Ky., 1888, at his home in McComb City, Miss., December 18, aged 37.

Lewis D. Marcum, M.D., Medical College of Ohio, Cincinnati, 1888, at his home in Portsmouth, Ohio, December 16.

Charles C. Cundall, M.D., New York University, at his residence in Fair Haven, Mass., December 16, aged 66.

William F. Farrell, M.D., New York University, 1886, at his home in New York City, December 23, aged 42.

Edgar H. Sugg, M.D., New York University, 1889, of Snow Hill, N. C., December 9, from dropsy, aged 33.

John A. Sneed, M.D., Tulane University, New Orleans, 1879, at Fairfield, Texas, December 16.

Walter S. Bunn, M.D., Columbus Medical College, Columbus, Ohio, 1884, at Lawrence, Kas.

Books and Pamphlets.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

BOOKS.

Hand Atlas of Human Anatomy. By Werner Spalteholz, Extraordinary Professor of Anatomy in the University and Custodian of the Anatomical Museum at Leipzig, With the Advice of Wilhelm His, *Professor of Anatomy in the University of Leipzig.* Translated from the Third German Edition by Lewellys F. Barker, Professor of Anatomy in the University of Chicago. With a Preface by Franklin P. Mall, Professor of Anatomy in the Johns Hopkins University at Baltimore. Vol. I. Bones, Joints, Ligaments. Paper; pp. 235. Price, $3.50. Leipzig: S. Hirzel. New York: G. E. Stechert. 1900.

Obstetrics. A Manual for Students and Practitioners. By David James Evans, M. D., Lecturer on Obstetrics and Diseases of Infancy, McGill University. Series Edited by Bern B. Gallaudet, M.D., Demonstrator of Anatomy and Instructor in Surgery, College of Physicians and Surgeons, Columbia University, New York. Illustrated with 149 Engravings. Cloth; pp. 430. Price, $1.75. Philadelphia and New York: Lea Brothers & Co.

Malaria According to the New Researches. By Professor Angelo Celli, Director of the Institute of Hygiene, University of Rome. Translated from the Second Italian Edition by John Joseph Eyre, M.R.C.P., L.R.C.S., Ire., D.P.H., Cambridge. With an Introduction by Dr. Patrick Manson, Medical Adviser to the Colonial Office. With Maps and Illustrations. Cloth; pp. 275. Price, $3.00. New York and Bombay: Longmans, Green & Co. 1900.

Disinfection and Disinfectants. A Treatise upon the Best Known Disinfectants. Their Use in the Destruction of Disease Germs, with Special Instruction for Their Application in the Commonly Recognized Infectious and Contagious Diseases. By H. M. Bracken, M.D., Professor of Materia Medica and Therapeutics, *University of Minnesota. Cloth; pp. 85. Price, $1.00.* Chicago: Trade Periodical Co.

The Care of the Consumptive. A Consideration of the Scientific Use of Natural Therapeutic Agencies in the Prevention and Cure of Consumption; Together with a Chapter on Colorado as a Resort for Invalids. By Charles Fox Gardiner, M.D., Non-Resident Fellow of the New York Academy of Medicine. Cloth; pp. 182. Price, $1.25. New York and London: G. P. Putnam's Sons. 1900.

A Practical Treatise on Medical Diagnosis for Students and Physicians. By John H. Musser, M.D., *Professor of Clinical* Medicine in the University of Pennsylvania. Fourth Edition, Revised and Enlarged. Illustrated with 250 Wood-cuts and 49 Colored Plates. Cloth; pp. 1105. Price, $6.00. Philadelphia and New York: Lea Brothers & Co. 1900.

Text-Book of Physiology. Edited by E. A. Schäfer, LL.D., F.R.S., Professor of Physiology, University of Edinburgh. Vol. II. Cloth; pp. 1365. Price, $10.00. Edinburgh and London: Young J. Pentland. New York: MacMillan Co. 1900.

Terapia delle Malattie del L'Infanzia ad uso di Medici e Studenti del Dott. Prof. Cesare Gattaneo. Libero docente di Clinical Pediatrica alla R. Universita di Parma. Cloth; pp. 507. Milano: Ulrico Hoepli. 1901.

Proceedings of the Kansas Medical Society. Thirty-fourth Annual Meeting, Topeka, Kan., Wednesday, Thursday and Friday, May 2, 3 and 4, 1900. Cloth; pp. 226. Topeka, Kan.: A. D. Bauer Printing Co. 1900.

The Australasian Medical Directory and Handbook. Edited and Compiled by Ludwig Bruck. Fifth edition. Corrected up to August, 1900. Cloth; pp. 221. Sydney: L. Bruck. London: Bailliere, Tindall & Cox. 1900.

Ethical Marriage. A Discussion of the Relations of Sex, from the Standpoint of Social Duty. By Delos F. Wilcox, Ph.D. Cloth; pp. 231. Price, $1.25. Ann Arbor, Mich.: Wood-Allen Publishing Company.

The Curious Case of Gen. Delaney Smythe. By W. H. Gardner, M.D. Cloth; pp. 204. London, New York and Montreal: The Abbey Press.

Transactions of the Texas State Medical Association. Thirty-second Annual Session held at Waco, Texas, April 24, 25, 26 and 27, 1900. Cloth; pp. 400. Austin, Texas: Von Boeckmann, Schutze & Co. 1900.

Report of the Commissioner of Education for the Year 1898-99. Vol. I. Cloth; pp. 1248. Washington: Government Printing Office. 1900.

The Practice of Medicine. A Text-Book for Practitioners and Students, with Special Reference to Diagnosis and Treatment. By James Tyson, M.D., Professor of Medicine in the University of Pennsylvania and Physician to the Hospital of the University. Secon[illegible] Revised and in Parts. Rewritten. With 127 [illegible] Colored Plates. Cloth. Pp. 1222. Price, [illegible] P. Blakiston's Son & Co. 1900.

Therapeutics: Its Principles and Practice. By Horatio C. Wood, M.D., LL.D. (Lafayette-Yale), Professor of Materia Medica and Therapeutics, and Clinical Professor of Diseases of the Nervous System, in the University of Pennsylvania. Eleventh Edition. Remodeled and in Greater Part Rewritten. By Horatio C. Wood, and Horatio C. Wood, Jr., M.D., Demonstrator of Pharmacodynamics in the University of Pennsylvania. Cloth. Pp. 850. Price, $5.00. Philadelphia and London: J. B. Lippincott Co. 1900.

The Medical Examination for Life Insurance and Its Associated Clinical Methods, with Chapters on the Insurance of Substandard Lives and Accident Insurance. By Charles Lyman Greene, M.D., St. Paul, *Clinical Professor of Medicine and Physical* Diagnosis in the University of Minnesota. With 99 Illustrations. *Cloth. Pp. 426. Price, $4.00. Philadelphia: P. Blakiston's Son* & Co. 1900.

Quiz—Compends. No. 16. A Compend of Diseases of the Skin. By Jay F. Schamberg, A.B., M.D., Professor of Diseases of the Skin, Philadelphia Polyclinic and College for Graduates in Medicine. Second Edition, Revised and Enlarged. With 105 Illustrations. Cloth. Pp. 291. Price, $0.80. Philadelphia: P. Blakiston's Son & Co. 1900.

Proceedings of the Eighth Annual Meeting of the Association of Military Surgeons of the United States, Held at Kansas City, Missouri, September 27, 28 and 29, 1900. Cloth. Pp. 376. Columbus, Ohio: Berlin Printing Co. 1900.

The Treatment of Fractures. By W. L. Estes, A.M., M.D., Director and Physician and Surgeon-in-Chief of St. Luke's Hospital, South Bethlehem, Pa. Cloth. Pp. 216. Price, $2.00. New York: International Journal of Surgery Co.

Diseases of the Nervous System. A Text-book for Students and Practitioners of Medicine. By H. Oppenheim, M.D., Professor at the University at Berlin. Authorized Translation by Edward E. Mayer, A.M., M.D., Pittsburg, Pa. First American from the Second Revised and Enlarged German Edition. With 293 Illustrations. Cloth. Pp. 900. Price, $5.00. Philadelphia and London: J. B. Lippincott Co. 1900.

Thomas [illegible] By Joseph Frank Payne, M.D., Oxon. Fellow and [illegible] of the Royal College of Physicians. Cloth. P[illegible] New York: Longmans, Green & Co. 1900.

Transactions of the Second Annual Session of the Tri-State Medical Association of the Carolinas and Virginia, Held at The Charleston Hotel, Charleston, S. C., February 20, 21 and 22, 1900. Cloth. Pp. 315. Richmond, Va.: Williams Printing Co. 1900.

Proceedings of the Nebraska State Medical Society. Thirty-second Annual Session. 1900. Cloth. Pp. 356. Published by the Society.

Appendicitis and Its Surgical Treatment. With a Report of One Hundred and Eighty-five Cases. By Herman Mynter, M.D. (Copenhagen), Professor of Clinical Surgery in University of Buffalo, Buffalo, N. Y. Third Revised Edition. Cloth. Pp. 231. Price, $2.00. Philadelphia: J. B. Lippincott Co. 1900.

Sexual Debility in Man. By F. R. Sturgis, M.D., Formerly Clinical Professor of Venereal Diseases in the Medical Department of the University of the City of New York. Cloth. Pp. 432. Price, $3.00. New York: E. B. Treat & Co. 1900.

Orthopedic Surgery. A Handbook. By Charles Bell Keetley, F.R.C.S., Surgeon to the West London Hospital. Cloth. Pp. 539. Price, $5.50 net. London: Smith, Elder & Co. 1900.

Transactions of the State Medical Society of Wisconsin. For the Year 1900. Constitution and By-laws and List of Members. Cloth. Pp. 480. Madison, Wis. M. J. Cantwell. 1900.

PAMPHLETS.

A New Nasal Splint. Retinitis Albuminurica with Report of Cases. By Francis W. Alter, Toledo, Ohio. Reprints.

Cerebral Abscess Following Chronic Otitis Media Purulenta—Operation—Recovery. By William H. Dudley, M.D., Easton, Pa.

A Paper on English Spelling. By George D. Broomell. Paper: pp. 27. Price, $0.10. Chicago: Ben Franklin Company. 1900.

Iritis. By J. H. McCassy, M.A., M.D., Dayton, Ohio. Reprinted from Medical News.

An Essay on the Reduction of Obesity. With Special Reference to the Use of Granular Effervescing Salts of Vichy and Kissingen. By William T. Cathell, A.M., M.D., Baltimore. John Wyeth & Bro., Philadelphia.

Catalogue of Autograph Collections. The Property of William Ebbitt Mitchell, 251 West 43rd St., New York. Now offered for sale.

Microscopical Reproductions of the Blood and Bacteria. Directions for Preparing Specimens for Diagnostic Purposes, etc. Reed and Carnrick, Jersey City, N. J.

Miscellany.

Toxicity of Expired Air.—Experiments at the Hygienic Institute at Prague seemed to indicate that the air expelled from the lungs of guinea-pigs and dogs contained some toxic substance, in addition to the carbon dioxid, as the animals rapidly succumbed to its action. But further research demonstrated that the toxic action was due to the ammonia in the putrefying excreta in the cages. Formanek concludes from these experiments that the syncope and discomfort experienced in insufficiently ventilated or crowded rooms, are not due to any special toxins expired but are merely reflex disturbances in sensitive individuals, caused by the heat or disgust at the odors emanating from the crowd. Ammonia can be incriminated to a slight extent and carbon dioxid still less.—*Arch f. Hyg.* xxxviii, 1.

Glycosuria Consecutive to Extirpation of Pituitary Gland.—Extensive experimental research on dogs has demonstrated that partial or total resection of the cerebral hypophysis produces besides the inevitable cachexia, a pronounced and persistent glycosuria, accompanied by polyuria. Caselli observes in his preliminary communication to the *Rivista Sperim. di Freniatria* xxvi, 1, that this result agrees with the clinical observation that glycosuria is frequent in case of a tumor in the pituitary gland with or without acromegaly.

Eucain Versus Cocain for Medullary Narcosis.—F. Legueu, professor agrégé at Paris, used cocain exclusively in forty-eight operations performed under intraspinal anesthesia, and then substituted eucain in the succeeding nine. His experience with the latter was very favorable. He has long employed it for local anesthesia in preference to cocain, on account of its lesser toxicity and the possibility of effectively sterilizing it by the usual methods. Whether eucain or cocain, he always uses a 2 per cent. solution. The average dose of cocain was 2 cgm., i.e., 1 c.c. of a 2 per cent. solution, but in a few cases he increased this amount to 3 cgm. and in others 1 cgm. proved sufficient. Dr. F. Engelmann reports an unfortunate experience with eucain B. in his own person, in a communication to the *Muench. Méd. Woch.* of October 30. He had 1 cgm. of eucain injected into the lumbar spinal cavity by a colleague by the usual technique; no anesthesia was induced, but symptoms of intoxication appeared in a few hours, severe sacral pains, headache, nausea and vomiting, eight to ten chills and slight temperature. The headache was unbearable at first. and persisted severe for eight to ten days, although not interfering with his duties. He found no relief from antineuralgics, but the headache ceased in the dorsal decubitus.

Societies.

Medical Association of Nevada, Reno, Jan. 7, 1901.
Pan-American Medical Congress, Havana, Cuba, Feb. 4, 1901.
Tri-State Medical Association of the Carolinas and Virginia, Richmond, Va., Feb. 26, 1901.

The Salt Lake (Utah) Medical Society, at its meeting, December 10, elected Dr. Ira A. E. Lyons, president; Dr. Alexander C. Ewing, vice-president; Dr. Murray R. Stewart, secretary, and Dr. Augustus C. Behle, treasurer.

The Columbus (Ohio) Academy of Medicine held its annual meeting, December 17, at which the following officers were elected: Dr. James C. Lawrence, president; Dr. Hugh Hendrixson, vice-president; Dr. John L. Gordon, secretary, and Dr. Francis W. Blake, treasurer.

The Jefferson County (Ala.) Medical Society held its last meeting for the year, at Birmingham, December 17, at which the following officers were elected: Dr. W. E. B. Davis, president; Dr. Edward P. Riggs, censor, and Dr. James M. Mason, health officer.

The Butler County (Ohio) Medical Society, at its meeting at Hamilton, December 12, elected Dr. August Schumacher, Hamilton, president; Dr. James E. Torrence, Oxford, vice-president; Dr. Edward H. French, Hamilton, secretary, and Dr. Francis M. Fitton, Hamilton, treasurer.

The Central District Medical Association of Iowa held its twenty-sixth semi-annual meeting at Boone, December 18, and elected Dr. David N. De Tar, Boone, president; Dr. Josiah D. McVey, Lake City, vice-president, and Dr. George H. Stranger, Boone, secretary and treasurer.

The New York Academy of Medicine held its annual election of officers, December 20, with the following result: Dr. Robert F. Weir, president; Dr. Charles M. Dana, vice-president; Dr. John H. Huddleston, corrsponding secretary, and Dr. Louis F. Bishop, recording secretary.

The South Texas Medical Association held its semi-annual meeting at Houston and elected Dr. Robert W. Knox, Houston, president; Drs. Walter Shropshire of Yoakum, and George W. Emory of Anderson, vice-presidents, and Dr. D. Stuart Wier, Houston, secretary and treasurer.

The Lorain County (Ohio) Medical Society, at its meeting held December 18, elected Dr. William C. Bunce, Oberlin, president; Dr. Ewan Cameron, Lorain, vice-president; Dr. A. M. Webster, Lorain, secretary, and Dr. Frank Young, Lorain, treasurer and librarian.

The Hawaiian Medical Association, at a recent meeting, changed its name to "The Hawaiian Territorial Medical Society." and elected the following officers: Dr. W. E. Taylor, president; Dr. H. C. Sloggett, vice-president, and Dr. A. G. Hodgins, secretary and treasurer.

The Montgomery County (Ohio) Medical Society met for its annual session at Dayton, December 7, and elected Dr. John S. Beck, president; Dr. Francis C. Gray, vice-president! Dr. Horace Bonner, secretary; Dr. David C. Lichilter, treasurer, and Dr. Duff W. Greene, censor, all of Dayton.

The Medical and Surgical Society of Montgomery County (Ala.) met at Montgomery, December 15, and elected Dr. Robert Goldthwaite, president; Dr. Frank H. M. McConnico, vice-president; Dr. Charles T. Pallard, secretary; Dr. Shirley Bragg, treasurer and county health officer, and Dr. Glenn Andrews, censor.

The Berrien County (Mich.) Medical Society met for its third annual session at Benton Harbor, December 13, and elected Dr. Henry V. Fulton, Benton Harbor, president; Dr. Robert Henderson, Buchanan, vice-president; Dr. Wakeman Ryno, Benton Harbor, secretary, and Dr. Hattie G. Schwendener, St. Joseph, treasurer.

The Northwest Arkansas Medical Society convened at Siloam Springs, December 11, and elected Dr. Thomas W. Blackburn, Boonsboro, president, and Dr. Joseph T. Clegg, Siloam Springs, secretary. Prairie Grove was selected as the place for the next semi-annual meeting in June, 1901.

The Tennessee Valley Medical Society met for organization at Huntsville, Ala., December 19, and elected Dr. Felix E. Baldridge, Huntsville, president; Drs. Thaddeus A. Casey, Albertville, and F. F. Pettey, Decatur, vice-presidents; Dr. Thomas E. Dryer, Huntsville, secretary, and Dr. Edgar Rand, *Leighton, treasurer.*

The Northwestern Ohio Medical Association, held its annual meeting at Toledo, December 14. The following officers were elected: Dr. John A. Wilkins, Delta, president; Drs. Harbon B. Gibbon, Tiffin, and Manford M. Hixson, Continental, vice-presidents; Drs. Joseph P. Baker, Findlay, secretary, and Theodore M. Gehrett, treasurer, were re-elected.

The North Texas Medical Association, which held its semi-annual session at Sherman, December 11, 12 and 13, decided to hold its next meeting in Paris. Dr. Robert F. Miller, Sherman, was elected president; Dr. Jesse B. Shelmire, Dallas, vice-president; Dr. Stephen A. D. Moore, Van Alstyne, secretary, and Dr. Carey A. Gray, Bonham, treasurer.

The Somerville (Mass.) Medical Society, at its annual meeting held December 13, voted to tender its cöoperation to the board of health in the proposed medical inspection. The following officers were elected: Dr. George A. Miles, president; Dr. Frederick G. Smith, vice-president, and Dr. Arthur R. Perry, secretary and treasurer.

The Morgan County (Ill.) Medical Society met at Jacksonville, December 13. The following officers were elected: Dr. John G. Franken, Chandlerville, president; Dr. Alonzo F. Burnam, Jacksonville, vice-president; Dr. E. F. Baker, Jacksonville, secretary; Dr. Edward Bowe, Jacksonville, treasurer, and Dr. William C. Cole, Jacksonville, librarian.

The Seaboard Medical Association of Virginia and North Carolina, held its annual meeting at Weldon, N. C., December 14 and 15. Norfolk, Va., was selected as the next place of meeting. Dr. J. Emmett Sebrell, Courtland, Va., was elected president; Drs. H. Turner Bass, Tarboro, N. C., Emerson Land, Oceana, Va., Joel Crawford, Yale, Va., and Albert R. Anderson, Wilson, N. C., vice-presidents; Dr. Isreal Brown, Norfolk, Va., treasurer; Dr. John R. Bagby, Newport News, Va., secretary, and Dr. A. K. Taylor, Washington, N. C., orator.

The Salt Lake County (Utah) Medical Society met at Salt Lake City, December 10, and discussed vaccination. The general consensus of opinion was that absolute immunity from smallpox, by vaccination, could be secured only by revaccination every time there was an epidemic. The following officers were then elected: Dr. Ira C. E. Lyons, president; Dr. Alexander C. Ewing, vice-president; Dr. Murray R. Stewart, secretary, and Dr. Archibald A. Kerr, treasurer.

The Calhoun County (Mich.) Medical Society, at its annual meeting held December 18, at Battle Creek adopted a resolution that it should be considered a violation of medical ethics for a physician to allow his name to be published in connection with reports of accidents or cases treated. The following officers were elected: Dr. Leon M. Gillette, Battle Creek, president; Drs. George C. Hafford, Albion, and John C. Brown, Burlington, vice-presidents; Dr. William H. Haughey, Battle Creek, secretary; Dr. Richard M. Olin, Battle Creek, treasurer.

The Maine Academy of Medicine and Science held its forty-second stated meeting at Portland, December 10, at which the following resolution was adopted: *Resolved*, That we, the members of the Maine Academy of Medicine and Science, recognizing the necessity of a public laboratory in this state, whereby contagious and infectious diseases can be studied and the public protected, do recommend and advise the establishment of such an institution and that legislation be enacted to that effect. *Resolved*, That this resolution be forwarded to the secretary of the State Board of Health, after being signed by our president and secretary. The election of officers resulted as follows: Dr. Samuel J. Bassford, Biddeford, president; Dr. Daniel Driscoll, Portland, recording secretary; Dr. Addison S. Thayer, Portland, corresponding secretary, and Dr. Herbert F. Twitchell, Portland, treasurer.

The Detroit Medical Society held a "centenary meeting" December 19, at which a symposium on the medical progress of the nineteenth century was offered. Dr. Victor C. Vaughan, Ann Arbor, who spoke on the progress of medicine, acknowledged the great advances made that have banished the fear of smallpox, reduced the death-rate in typhoid fever from 30 to 7 per cent., discovered the causes and partial cures for tuberculosis, anthrax, cholera and the like. He said that isolation and antiseptics had more to do with reducing the danger from communicable diseases than all other agencies. He predicted that the day is coming when science will be so absolute that no man will pollute the water we drink, the food we eat, the air we breathe and the floors and pavements on which we live and walk, and that disease in large part will be utterly stamped out. Dr. Nathaniel W. Webber spoke of "The Old Doctors of Detroit and Michigan," and Dr. Henry O. Walker discussed the progress of surgery, accrediting to American surgeons the greatest and most wonderful advances of the century. Frank T. Lodge read a paper entitled "A Half Century of Medical Jurisprudence," in which he condemned the existing practice of buying expert witnesses in cases at law. He suggested possible remedies: That experts be named by the court in every case; that one be selected by each party to the case and a third by the court; that a standing commission be appointed, from which experts could be drawn; that there be an auxiliary panel of experts, a part of the jurors to be drawn from them; that there be an abolition of hypothetical interrogations; that there be a severe restriction in the way of examinations for eligibility as experts and that the payment of experts be made out of the public treasury.

THIRD PAN-AMERICAN MEDICAL CONGRESS.

SECTION OF OBSTETRICS.

Dr. E. Gustave Zinke, 13 Garfield Place, Cincinnati, Ohio, Secretary. Titles and authors of papers received up to date: 1. The Toxicity of the Urine in Pregnancy and Its Relation to Puerperal Convulsions; by Dr. John Milton Duff, Pittsburg,. Pa. 2. Face Presentation; by Dr. J. A. Lyons, Chicago. 3. The Management of a Myomatous Pregnant Uterus; by Dr. W. H. Wathen, Louisville, Ky. 4. Experimental Investigation on Puerperal Sepsis; by Dr. F. Gaertner, Saginaw, Mich. 5. The Simultaneous Occurrence of Extra- and Intra-Uterine Pregnancy and a Tabulated Record of 62 Cases Collected from 1708-1901; by Dr. E. Gustav Zinke, Cincinnati, Ohio. 6. Cholemia and Hemorrhage; by Dr. David Tod Gilliam, Columbus, Ohio. 7. Renal Insufficiency in Relation to Women; by Dr. Jas. T. Jelks, Hot Springs, Ark. 8. Clinical Consideration Relating to Cancer of the Uterus; by Dr. A. T. Currier, New York City. 9. The Medication and Treatment of Uterine Fibroids; by Dr. W. B. Chase, New York City.

Philadelphia College of Physicians.

Meeting November 20, 1900.

DR. S. D. RISLEY in the chair.

ORBITAL ABSCESS.

DR. S. D. RISLEY exhibited a case of abscess of the orbit following injury which was associated with an opening in the ethmoid cells caused by a blow from a piece of metal on the nasal aspect of the upper eye-lid. Cold compresses were applied, but later fluctuation occurred, and after a deep incision was made a large amount of pus was evacuated. The cavity was syringed with peroxid of hydrogen and saturated solution of boracic acid. It was found that the fluid passed freely into the nostrils.

PAPILLOMA OF CARUNCLE.

DRS. W. C. POSEY and E. A. SHUMWAY had only been able to find five cases of this condition that had been accurately described microscopically, and this case was the sixth. The patient was a man aged 60 years, who exhibited a mulberry growth attached by a pedicle to the right caruncle, and two similar growths on the palpebral conjunctiva near the lid margin. The growths were incised and the loss of tissue replaced by a flap from the forehead. Microscopic examination showed a pedicle of connective tissue attached to the caruncle, from which proceeded numerous branches covered with a thick mantel of epithelium. The axial connective tissue was embryonal in character, and contained thin blood-vessel walls. There was a marked increase of lymphoid cells, and numerous goblet cells in the epithelium covering the caruncle and the mantels covering the tumor. There was no extension of the growth beneath the surface of the caruncle.

DR. GEORGE E. DE SCHWEINITZ referred to a case of papilloma springing from the plica semilunaris which he had removed last April.

DR. C. A. VEASEY had several years ago removed a growth which he thought was a papilloma, but which proved to be a sarcoma.

INTRAOCULAR METALLIC BODIES.

DR. GEORGE E. DE SCHWEINITZ described two cases of intraocular metallic foreign bodies which had been localized with the X-rays according to Sweet's method. In one case the body was firmly imbedded in a mass of cicatricial tissue behind the ciliary body, where it had been for ten months. It could not be removed with a magnet and the eyeball was removed as sympathetic inflammation had already set in. In the second case the foreign body was of unusual size and was easily removed twenty-four hours after the accident. The eyeball was collapsed; it was filled with normal saline solution and closed with catgut sutures and there was an uninterrupted recovery. He dwelt on the uselessness of attempting to remove a foreign body by a magnet after it had become imbedded and was of long standing.

INFLUENZA AND GLAUCOMA.

The speaker also read a paper on the etiological relationship of epidemic influenza to chronic glaucoma. Some writers had stated that glaucoma was more prevalent after epidemics of influenza. He related a case of retrobulbar neuritis caused by this disease in which he had observed the formation of a cup closely simulating glaucoma, and this condition might account in some cases for this supposed relationship.

DR. M. H. FENTON had seen a case diagnosed influenza, and on the sixth day the eye was of stony hardness, while the other eye exhibited chronic glaucoma. He believed the superintoxication in influenza induced glaucoma in eyes predisposed to the disease.

CONJUNCTIVAL HEMORRHAGE.

DR. HOWARD F. HANSELL reported a case of hemorrhage from the conjunctiva in an infant. The child at birth was frail, and for several days after birth there had been a purulent discharge from the conjunctiva of both lids. Two weeks later bleeding from the conjunctiva commenced and continued five days. The hemorrhage came from the entire conjunctival surface and continued day and night. The blood count showed 5,400,000 red and 5600 white corpuscles; the hemoglobin was not estimated. Death ensued at the fifth week.

DR. DE SCHWEINITZ recalled two cases of a similar nature, one of which he had reported.

Cincinnati Academy of Medicine.

Regular Meeting, Nov. 25, 1900.

GALL-STONES.

DR. RUFUS B. HALL presented some gall-stones, removed from a woman 37 years old, the mother of thirteen children, the youngest being but 7 weeks old. Her present illness began suddenly five weeks ago with what was at first supposed to be an attack of gastralgia; in a day or two, however, she commenced to have severe chills every day or even oftener, followed by profuse and exhausting sweats. At this time there was noted an enlargement of the upper part of the right abdomen extending downward below the free border of the ribs some three or four inches. She entered the Presbyterian Hospital one week ago; at that time she was delirious, her pulse was between 150 and 160. Soon after her entry she was taken with a chill which sent her temperature to 105. The abdominal enlargement had increased to about the size of an adult head. Suspecting a suppurating gall-bladder or an abscess of the liver, he aspirated and drew off a large quantity of pus. This he knew to be from the gall-bladder, as during the aspiration he could feel the stones therein. Within twelve hours she had improved greatly and at the end of fifty hours she could answer questions intelligently. He then operated, removing something over 850 gall-stones.

DR. J. L. CLEVELAND narrated a case that had come under his observation a number of years ago. The patient had had an intermittent fever for a long time which could not be controlled by quinin or arsenic. There was no jaundice, no enlargement over the liver, no tenderness, only a gastro-intestinal catarrh that might have been present in any fever. The gall-bladder could not be outlined. The patient went on from bad to worse, finally died, and on post-mortem examination the gall-bladder was found to be filled with stones.

FIBROCYSTIC TUMOR OF THE UTERUS.

Dr. E. Gustave Zinke presented a specimen of fibrocystic tumor of the uterus that in some respects resembled a pregnancy. The physical characteristics of the tumor were those of a pregnant uterus, but the history of the case was of longer standing than nine months. Even on opening the abdomen the tumor at first sight greatly resembled a pregnant uterus. Tumor was removed and the woman has made an uneventful recovery. Dr. Zinke also presented a specimen of multilocular cyst of the ovary with a pedicle thirteen inches in length. There were papillomatous masses within, but he did not think there would be any recurrence on that account. Recovery uneventful.

Dr. C. L. Bonifield presented a specimen of fibrocystic tumor of the uterus in which the uterus itself had participated in the cystic degeneration. In this case the cervix was much elongated, so much so that it protruded from the vulvar orifice. This specimen simply showed a more advanced stage of the disease than Dr. Zinke's tumor. Dr. Bonifield also presented a specimen of multilocular ovarian cyst with papillomatous ingrowths. This specimen was very much like that of Dr. Zinke's before it was opened.

LUNG WITH UPPER LOBE COLLAPSED.

Dr. W. D. Haines presented this specimen. Post-mortem examination was made some 18 to 20 hours after death; rigor mortis was absent; post-mortem staining was well marked, especially along the dorsal surfaces. Right kidney was enlarged and the kidney congested; the left kidney was normal. The liver was greatly enlarged. After the abdominal viscera had been removed there was noticed a marked bulging in the left hypochondriac region. On introducing the canula there escaped from five to six pints of mucopurulent fluid containing numerous flocculi. The pus-sac was in all probability tubercular. There was, as shown in the specimen, complete collapse of the upper lobe of the lung.

INTESTINAL OBSTRUCTION DUE TO INTUSSUSCEPTION.

Dr. Louis E. Cook reported this case, a girl 7 years of age, well developed and nourished. He was called first on the morning of June 28, and found her vomiting and complaining of cramps in the right side of the abdomen. The attack was sudden, as she had gone to bed the night before perfectly well. Pain was so severe that palpation of the abdomen was impossible. There was no fever. Vomitus was chiefly of mucus. A provisional diagnosis of intestinal indigestion was made, and hot applications were ordered to the abdomen and calomel and soda internally. During the day the bowels were moved by large enemata. Vomiting almost continuous, accompanied by much retching. On June 29 she passed a very bad night, pain continuous, no sleep; vomiting persisted during the day. On June 30, pain somewhat diminished, so that for the first time an examination of the abdomen could be made. Small elongated mass could be detected in the right iliac region; abdomen flat. Rectal examination was negative. Diagnosis changed to intussusception and a high enema given, with, however, no result. On July 1 she passed a restless night, better, however, than the preceding, the vomiting ceasing for about six hours. At 7 in the morning vomiting began again, becoming bilious. An enema was given at a temperature of 105 degrees, with high pressure from a fountain syringe, the patient being in the knee-elbow position. About one and one-half gallons of water were used. Vomiting was incessant during the injection. After the enema she passed some small, soft fecal masses and a large amount of gas, the first since the beginning of her illness. Vomiting stopped until evening, and it was then very slight. Mass in iliac region had disappeared. On July 2 child passed a fairly good night; vomiting stopped; bowels moved once. During the day rectal alimentation of peptonized milk was begun. She began feeding by the mouth by the 4th. and on the 8th of the month was able to take solid food. The temperature throughout the attack was seldom more than 1 degree above the normal.

Omaha Medical Society.

Regular Meeting, Nov. 27, 1900.

LEUKEMIA.

Dr. B. F. Crummer read a paper on this affection, and presented the subject. He was 32 years of age, of good family history. He was a man of good habits and denied any venereal history; he suffered with mild malaria in 1896, with nosebleed in 1898. During 1898 and 1899 he was very weak, had a rapid pulse and much dyspnea. He first came under observation Nov. 1, 1900. He was a basket-maker and went to the Missouri bottoms in May last to gather his material. In June he had to abandon his work and suffered with pain in the abdomen, anorexia, fever, night-sweats and loss of weight; his pulse was about 110, his temperature 101. There were mucous râles, and the inspiratory sounds were harsh; there was a soft, systolic murmur over the base. The spleen was much enlarged, notched, and reached downward to the crest of the ilium and one inch beyond the navel. The axillary, and inguinal glands were slightly enlarged; there was no tenderness of the tibia. He had been using Fowler's solution in doses of 15 or 16 drops for three or four weeks; he was now able to work a little; his temperature is still from 101 to 102 daily. There was an average of one white blood-cell to 12 or 15 red cells; hemoglobin was 45 per cent.; the myelocytes were in large proportion, about 12 per cent.; the bone-marrow was certainly involved, though the tibia was not tender. This patient was dangerously near the most grave proportions of the white and red blood-cells. The patient was doing well on the arsenic and the extract of bone-marrow. Another case, seen in 1892, showed the blood-cells in the proportion of 1 to 5 and the abdomen was entirely filled with the enlarged spleen; the patient lived two years. The Doctor had also treated a woman of 36 in 1896 who had marked pain and tenderness of the tibiæ; she had the lieno-myelogenous variety of leukemia, and improved under large doses of arsenic.

ICTERUS NEONATORUM.

Dr. H. M. McClanahan read this paper. Jaundice in the neonati is frequently observed; usually passes away in a few days without injurious effects, and is rarely a symptom of serious import. Of these cases, there are two classes: one, with recovery, without untoward symptoms; the other, in which other symptoms of disease are shown or the patients fail in strength. The first class is usually called physiologic, benign, pseudo or hematic in origin; the other, is called hepatic in origin. The red blood-cells are rapidly reduced in number, hemoglobin is liberated, converted into biliary coloring matter and carried to the intestinal tract. If the infant is very feeble or the skin surface is chilled, this coloring matter is deposited in the skin.

Quincke's theory is that the ductus venosus remains pervious and the blood from the portal vein, laden with bile pigment, is carried into the general circulation. These infants are always unusually feeble. The other class, the fatal cases, are called pathologic, or malignant icterus. Among the causes are congenital defects, or absence of the bile-ducts. Dr. White reported 18 cases in which there was an absence of either the hepatic duct or the common duct, or the latter had become an impervious cord. Cases have also been seen at autopsy in which the cause was due to pressure upon the ducts by a neoplasm. Syphilitic hepatitis is also a cause of jaundice. Reliable authorities report cures of intense jaundice under antisyphilitic treatment. Jaundice is often associated with sepsis due to a phlebitis of the umbilical vein which has hepatitis. The practical side of the subject is that the physician shall be able to differentiate between the benign and the malignant cases: in the former there are no serious symptoms: the stools are not clay-colored, the urine does not stain the napkin, there is no fever, no loss of weight; in the latter the icterus gradually becomes more intense, the eyes and the mucous membrane of the mouth gradually become icteric, the urine is dark, often scanty, and the stools white or clay-colored; the liver is enlarged; the temperature is often subnormal. Of greatest importance, however, is the gradual loss of weight in spite of the fact that the child takes an abundance of food. Syphilitic jaundice is rare, though the liver is often affected by syphilis; the diagnosis must be made from the history of the mother; miscarriages and still-births strongly point to this cause; in this form the liver is enlarged from birth, whereas, in obstructive jaundice, it gradually enlarges during the course of the disease. Jaundice due to sepsis usually appears later and has with it fever, anorexia, twitchings, tonic contractions or convulsions, and gastro-intestinal trouble. In sepsis accompanied by icterus there is frequently hemorrhage from the navel or bowels.

Dr. J. M. Aikin presented a brain and gave the following very interesting history: The man, aged 50, came to him in May, 1899, after an attempt at suicide. He was under treatment two months for persistent pain in the vertex; he admitted an almost irresistible impulse to suicide; there were no delusions. He was a man of large business, neither used liquor, tobacco nor drugs. There was no history of prior sickness; he gave up his business and traveled, improved, came back and resumed business. Later the headache returned; on the 24th the suicidal impulse again overpowered him. He wrote a letter with regard to it, and sent out three messenger boys, each having 10 cents for morphin; it is supposed that he got about 7 or 8 grains. He took all the powders, closed the room tightly and turned on the gas. He was found the next morning. After vigorous efforts, he was restored. On Sunday he was rational, doing well, apparently recovering. He said there had been no business reverses, no trouble, merely a return of the awful headaches with the irresistible impulse to suicide. On the 25th preparation was made to send him to the asylum; on the 26th his temperature was 103, respiration was about normal; he became worse, and died on the morning of the 27th. An autopsy showed that death was due to hypostatic pneumonia, a late result of the gas poisoning. The brain showed the source of the headaches and the suicidal impulses; the dura was strongly adherent for 3 inches back of the fissure of Rolando; calcareous matter was present. There had been no brain hemorrhage; degeneration was shown in the region supplied by the middle cerebral artery; there had been no paralysis.

ACQUIRED DEXTROCARDIA.

Dr. Homer M. Thomas demonstrated a case of the above. A consideration of the general subject of heart displacement reveals two varieties—the congenital and acquired. Of acquired displacements, it is found that very considerable displacement of the apex-beat to the right may be due to retraction of the right lung from fibroid phthisis. Again, a very common cause is found in the development of pneumothorax. In cases of fibroid phthisis where dextrocardia exists, frequently the apex-beat is above the right nipple, and might be recognized by physical signs dependent upon collapse of fibrosis of the lung. The heart is pressed out of position by effusions of fluid—inflammatory, serous, or bloody—into either pleural cavity; by pneumothorax of either side; by intrathoracic tumors; by hypertrophous emphysema, or other causes of enlargement of the lung; by extensive pneumonic consolidation, or by abundant pericardial effusion of any kind. Certain conditions of the abdominal contents produce a similar effect, for example, gaseous distention of the stomach and intestines; enlargement of the liver and other solid organs; abdominal tumors of all kinds, and ascites when considerable.

In displacement of the heart toward the right, the condition is usually the result of effusion into the left pleural cavity; of contracting processes of the right lung or pleura; of left pneumothorax; and of tumors of the left side of the chest, or of the mediastinum. In extreme cases the heart may be displaced toward the right side until the impulse is found in the axillary region.

M. F. J., aged 46, a rubber-worker. His duties involved the inhalation of considerable quantities of soapstone, as well as carbon bisulphid for seven years. There is no family history of tuberculosis, neither of his having had pneumonia or pleurisy. His only sickness of recent date was an acute rheumatism in 1895. Present condition reveals a cough, shortness of breath, which begun seven years ago. He has had much headache, and pain in the left chest throughout his illness. For two years the cough was very dry; at present expectoration is abundant, and comes in somewhat paroxysmal seizures. No tubercle bacilli have been found. The injection of tuberculin developed absolutely no reaction.

Inspection shows general anemia; some debility; dyspnea. Complexion dark; emaciation moderate. Chest bulging at costo-chondral junction; respiratory movement hurried; restricted intercostal retraction. Apex-beat, fifth space, right nipple line; upper border, upper fifth rib. Right border, anterior axillary line. Left border, right border of sternum. Lower, contiguous with the liver.

Height, 5 feet, 8 inches; weight, 124 pounds. Tape measures: Right lung, expiration, 17 1/2 inches; inspiration, 18 inches. Left lung, expiration, 16 3/4 inches; inspiration, 17 inches. Combined expiration, 34 1/4 inches; inspiration, 35 inches. Temperature in the morning 97.5; noon, 98; and evening, 98. Pulse, 92; rhythm, regular. Heart: Valvular sounds clear; moderate thickening of arteries. Upon percussion of left lung anteriorly dulness is found extending from the supraclavicular, clavicular, and infraclavicular regions. Upon the right lung anteriorly there is hyper-resonance, which extends from the lower border of the first rib down to the lower border of the third rib in a semicircular line about one inch to the right of the costosternal articulation. Posteriorly, the lower border of the right lung shows increasing dulness extending from the lower border of the eleventh rib up to the inferior border of the sixth rib posteriorly. Posteriorly, in the right lung, extending downward from the superior border of the fourth rib down to the eighth rib anteriorly, typical bronchial breathing with moist, fine bubbling râles and increased vocal fremitus are found. There is great dyspnea upon exertion in city air, less so in country air. This is aggravated after eating a hearty meal. Patient has chronic constipation, bowel movement about once in five days. This condition has resisted treatment as to curative results. The constipation is doubtless due to mechanical engorgement of the lower bowel and rectum. The author's conclusions, based upon the history as well as the present clinical findings, are that the case is one of acquired dextrocardia, due to fibroid phthisis and an antecedent attack of pleural pericarditis.

Treatment consists in removing the exciting cause of the dextrocardia, and, necessarily, the displacement would tend to correct itself. This general principle of treatment can be applied to only a limited extent in this case. The exciting cause is of too chronic a character, and the lesions resulting from the same too permanent, to admit of entire removal. Treatment is therefore mainly directed toward maintenance of the best possible physical condition, and the relief of acute symptoms as they may arise.

COMPLETE TRANSPOSITION OF VISCERA, INCLUDING LUNGS.

Dr. George W. Webster reported a case of this kind. He believes the lungs are transposed, for the following reason: On account of its size, and the angle at which the right bronchus is given off, and possibly for other reasons, the percussion sound on the right side in the infraclavicular space is slightly higher in pitch. In the same situation the normal respiratory murmur is slightly harsher in quality and raised in pitch, and the normal vocal resonance is increased there. In this case the normal disparity is reversed, warranting the conclusion that the lungs are transposed. Congenital anomalies and malformations of the heart are interesting. Recently Féré has demonstrated that marked modifications in development may be produced in the chick by injecting pathogenic germs and toxins into eggs undergoing incubation. These experiments show that agents which produce disease during extrauterine life, and later intrauterine existence, give rise to malformations during the earlier phase of existence. Ballantyne puts it thus: "The same causes are in action in both periods, but when influencing an embryo so far developed as to have specialized organs, the result is disease. When, on the other hand, influencing an embryo, in which such specialization has not been carried on to the same extent, the result is a malformation. In the one case the results are pathological; in the other, teratological." Causes of congenital diseases and malformations are similar and may be identical. Among internal displacements, transposition of the viscera is perhaps the commonest. Dextrocardia may be present without transposition of the viscera, but such cases are rare.

Two hypotheses have been proposed in explanation of this anomaly. Dr. Frazier suggests that the transposition may be due to the subject having been one of twins which were developed from a single ovum, and in which dichotomy was complete. Von Baer has found that in a few instances the embryo lies with its left side directed toward the yolk, whereas the right side is normally in this position.

Dr. Robert H. Babcock stated that he was interested in the subject of dextrocardia, both congenital and acquired, and in his early practice he encountered four cases within two years. Autopsies were made in two of them. He was much interested in the manner in which the heart could become displaced so extensively to the right. There must be some rotation of the heart, and in looking up the subject he found there was great diversity of opinion expressed on that point, some maintaining that as the heart was pushed over to the right, it rotated on its long axis in such a manner as to bring the left ventricle to the front and the right chambers farther to the right and posteriorly, others maintaining again that the heart rotated on its long axis so as to bring the right chambers more to the front and the left chambers more to the rear than they are normally. In one of his cases, a boy, 3 or 4 years of age, the heart was extensively displaced to the right in consequence of retraction of the right lung and pleuro-pericardial adhesions. There were systolic murmurs over the base of the heart, and he believed them to be vascular. At the autopsy it was found that the heart had rotated so that the right chambers came well to the front and over toward the left side, and the superior vena cava and innominate were drawn across the aorta in such a way as to produce a very considerable obstruction to the arch of the aorta. This obstruction had led to extreme dilation of the left ventricle. There were also hypertrophy and dilatation of the right ventricle in consequence of tension in the pulmonary artery.

The second case of his series that came to autopsy was a young man who died of tuberculosis, in whom the left lung was found absolutely destroyed, the left half of the thorax converted into a huge pyopneumothorax, the bronchial tubes cut off and sealed, and that half of the chest containing about a pint of sweet-smelling pus, the walls being lined with cheesy material. The heart was displaced to the right side, and there were tubercles upon the pericardium. The right lung was contracted, more or less cirrhotic, drawn back and reduced in size. The heart was rotated in the opposite direction, the left chamber coming more to the front, producing considerable twist in the axis of the aorta, stretching the arteries and veins in a peculiar fashion, producing considerable tension and increase of blood-pressure, but there were no murmurs, such as are recognized in many cases of anemia, and which in those days he regarded as hemic murmurs.

The first case he happened to see of the series was a man who had a pronounced cirrhosis of the right lung; the heart lay absolutely horizontal in the right half of the thorax, and completely uncovered by lung.

The subject of congenital dextrocardia is more interesting from a pathological than a clinical standpoint. He had seen a recent statement to the effect that cases of congenital dextrocardia were apt to die of pulmonary tuberculosis. This interested him, because in the last case that came under his observation he had an opportunity to notice the development of pulmonary tuberculosis about a year after he examined the woman, although there was no tubercular history in the family. She came to him on account of heart-beat in the right side. There was no indication that that girl would develop pulmonary tuberculosis. When he saw her a year afterward she had pronounced pulmonary tuberculosis with bacilli in the sputum.

Dr. George W. Webster said that in 1875 Rokitansky, of Vienna, wrote his famous monograph on congenital cardiac malformations, and in it he pointed out that these congenital malformations of the heart are very likely to lead ultimately to either general or pulmonary tuberculosis. This statement has been shown to be too broad. It is well-known that congenital lesions, where they affect the pulmonary orifice, practically always lead to either general or pulmonary tuberculosis on account of the anemia of the lungs, which is always induced as the result of the valvular lesion. The views of Rokitansky were too sweeping, and his statements applied only to cases of congenital stenosis of the pulmonary artery and not to other malformations. He had seen nothing in medical literature that he recalled at the present time, and he had gone over Peacock's work very carefully where there was any reference to complete transposition of all the viscera leading to pulmonary complications, or to the likelihood of patients dying earlier from the complication of pulmonary tuberculosis.

Dr. H. M. Thomas, in closing the discussion, said that with reference to the exciting cause of heart displacements of the acquired type, the case he had presented appeared to have acquired the dextrocardia during his seven years' work in a rubber factory where he inhaled considerable carbon bisulphid. The man was in perfect health when he entered the Morgan and Wright factory, and after seven years' labor therein his dyspnea became so great and paroxysmal cough so marked that he had to discontinue working, so that the influence of employment was one cause, and the specific effects of the inhalation of carbon bisulphid the other.

The Kings County Medical Association.

Stated Meeting, Dec. 11, 1900.

President Dr. H. Arrowsmith in the chair.

TREATMENT OF ACUTE DYSENTERY BASED ON ITS ETIOLOGY AND PATHOLOGY, WITH SPECIAL REFERENCE TO USE OF MAGNESIUM SULPHATE.

Dr. W. J. Cruikshank said that from January till December, 1897, 97,000 persons had been stricken with dysentery in Japan, and 70,000 had died. In one province there had occurred in 1890 801 cases, with 225 deaths, and in 1891, 8390 cases with 2163 deaths, or a mortality of a little over 26 per cent. Every country in Europe had paid a heavy tribute to dysentery. In the tropics this disease destroys more lives than cholera, and has been more fatal to armies than powder and shot. In France dysentery was accountable for 1/20 of the total mortality in the army, and in Algeria it represented 1/5 of the total mortality. In epidemics occurring in temperate climates the mortality varied from 7 to 15 per cent. In tropical epidemic dysentery the mortality was between 20 and 30 per cent., although even so high a mortality as 60 or 70 per cent. had been noted in certain epidemics. Military experience in the tropics showed that acclimatization had no effect on dysentery. According to Pepper, this disease was responsible for the death of 300,000 of the soldiers during our Civil War. The recent official reports from the United States army and navy did not give detailed information regarding dysentery during the late war with Spain. In the year 1898 there had been 368 deaths from dysentery in Greater New York, and in 1899, 267 deaths. The preponderance of evidence seemed to be in favor of the amebic theory as to the etiology of this disease. Bacteriologists were agreed that dysentery is the result of microbic infection, but opinion was divided as to whether it was the result of a specific micro-organism or of several bacteria.

The speaker expressed the opinion that the so-called varieties of dysentery were chiefly founded on mistaken ideas regarding the etiology and pathology of the disease. Dysentery had been frequently confounded with simple diarrhea and enteritis. One of the most misleading of these so-called varieties was that designated as malarial dysentery. Dysentery is one disease, and one only, whether observed in the tropics as endemic, or in the temperate regions as sporadic. Even so careful and conservative a writer as Flexner had expressed the opinion that the conclusions of bacteriologists which had led to the establishment of various types of the disease might not be strictly in accordance with fact. He was of the opinion that the causative agent of dysentery might not vary in these different types.

The reader of the paper expressed the belief that the underlying principle of treatment was purgation, in spite of the many statements of medical authorities to the contrary. The remedy he recommended was magnesium sulphate used in such a way as to secure depletion of the vessels, rather than purgation. He believed that this remedy was as nearly a specific for dysentery as quinin was in malaria, or mercury and potassium iodid were in syphilis. In all cases of acute dysentery, from the beginning of the attack until there was a subsidence of the symptoms, it should be administered in dram doses every two hours, dissolved in a very little water and mixed with a little aromatic sulphuric acid. If tympanites were present, it would rapidly subside under this treatment. At the end of forty-eight hours the stools would become biliary and feculent in the vast majority of cases. When the stools had become nearly normal the medicine could be gradually withdrawn. The average duration of the disease under such treatment was from three to seven days. The practitioner was often tempted in these cases to give a hypodermic injection of morphin to relieve the pain, but his experience had taught him that almost as great relief followed the use of the magnesium sulphate. By stimulating the naturally sluggish liver to greater activity the sulphate increased the biliary secretion, and in this way acted somewhat anti-septically, he believed, though he well knew that this was a mooted question in physiology. This remedy, by abstracting water from the tissues and pouring it into the intestine, depleted the mucous membrane, diminished the inflammatory process and rid the intestinal canal of the infectious material. The physiological action of this medicine had been known and appreciated for years by gynecologists and surgeons. Dr. Cruikshank said that his attention had been directed to this method of treatment by a case which he had treated some years ago, according to the plan then in vogue, that is, the alternate administration of sulphate of magnesium and opium. He had noted the great improvement in all the symptoms following the use of the sulphate and the return of the dysenteric symptoms when opium and bismuth had been given, but he had not had the courage to depart from this approved plan of treatment, and on calling in eminent counsel it had been indorsed as the proper one. The patient had died after ten days. The author gave copious citations from a number of medical authors who had found magnesium sulphate exceedingly useful, and vastly superior to the other remedies commonly employed. His conclusions were: 1, dysentery is a disease of great gravity: 2, it is both contagious and infectious: 3, it is caused by the introduction into the system through food and drink, and also through the air, of a specific micro-organism the identity of which seemed still in doubt: 4, dysentery is one disease in whatever latitude it is found, and the only varieties are those based on the intensity of the morbid process; 5, the therapeutic agents suggested for the treatment of acute dysentery are useless and often harmful, and magnesium sulphate acts as a specific.

Dr. Ira van Gieson called attention to the unfortunate tendency of the present time to unduly exalt the sphere of the laboratory in the study of the science of medicine. He had personal knowledge of the patient way in which the author had elaborated this subject, and was free to say that the therapeutic discovery contained in this paper had been made independently of others and without a knowledge of what others had previously done.

Dr. E. H. Bartley was disposed to differ from the author in his view that all cases of dysentery are true dysentery, not excepting acute colitis with bloody discharges. Cases were cited in illustration of this point. Again, most bacterial diseases are self-limited, but statistics and all our experience showed that this was not the character of dysentery. He also doubted the possibility of communicating the disease through the air, because the amebæ do not fly, and when dried up they are no longer contagious. Perhaps the author had not dwelt sufficiently upon the hepatic stimulation which results from the treatment which he advocates. Such stimulation was produced by strong saline solutions, especially solutions of sulphate of soda and magnesium. This increases the oxidation processes of the liver, and augments the activity of this organ as a destroyer of poisons, thus assisting the system to resist the action of the poisons thrown into the circulation by the pathological process. The treatment also caused a freer portal circulation and unloaded the small intestine. Dysentery was really a constipating disease, as there is constipation in the small intestine, and this gives rise to congestion and obstructed circulation in the rectum.

Dr. Jacob Fuhs said that this treatment was a rational one, which was shown not only by the results attained, but by its applicability to other infectious diseases. Nature's method of treating this disease was eminently eliminative, and it seemed strange that the profession should have fallen into the way of administering such remedies as were distinctly opposed to Nature's method. The only explanation that he could offer for this was that the great distress of patients suffering from dysentery had tempted physicians to resort to narcotics. It had been customary in the past to try to counteract the noxious effect of the narcotics by giving castor-oil: hence the popularity of the old opium and castor-oil treatment. He had found the sulphuric acid treatment useful. While he had had only a very limited experience with the treatment with magnesium sulphate, so far as it had gone it had been eminently satisfactory.

Dr. Lewis W. Pearson said that it had been his practice to begin the treatment of dysentery by giving a dose of magnesium sulphate or of castor-oil, and then follow this with opium, bismuth and muriatic acid. Recently he had tried another method—the giving of enemata of permanganate of potassium, using at first one quart of a 1 to 4000 solution, and later a 1 to 2000 solution. The latter strength had been kept up until the patients had nearly recovered. Recovery had been very prompt in each instance. He had been led to try this method because dysentery is a bacterial disease.

Dr. Cruikshank, in closing the discussion, said that there might exist an acute colitis from other causes, but such a case was not dysentery. The so-called varieties of dysentery were simply the result of the absorption of varying quantities of toxin. Dysentery was a specific disease and required a specific plan of treatment.

Cleveland Medical Society.

Regular Meeting, November 24, 1900.

President Dr. Henry S. Upson in the chair.

PRESENTATION OF CASES.

Dr. William E. Wirt presented a man on whom he had operated for club-foot. The deformity in this case was an extreme equinus with some degree of varus. He did a tenotomy of the Achilles tendon, following which he corrected the deformity by force. He showed that the result gave the man a fairly useful foot. He also presented a child 20 months old on whom he had successfully operated without cutting. He also presented a case of periostitis of the tibia in a boy 4 years old. He discovered that the lesion had a specific origin, and by using potassium iodid he had secured a good result.

CONGENITAL DISLOCATION OF HIP-JOINT, WITH ESPECIAL REFERENCE TO LORENZ'S BLOODLESS REDUCTION.

Dr. Walter G. Stern said that the congenital dislocation of the hip-joint has been considered quite rare, but as the knowledge of its curability is disseminated, the number of cases treated and reported has so increased that Hoffa says "it is the most common congenital affection." It is stated that 87.8 per cent. of cases occur in females: 1/3 are bilateral. The most frequent dislocation is upward and backward upon the dorsum ilii. An acetabulum is always present, mishapen and generally filled up with connective tissue. The muscles are distorted, the pelvis flattened and tilted, sometimes enough to cause obstruction to labor.

The symptoms are limping or waddling gait—explained by Trendelenburg as an adduction gait, in which the side of the pelvis opposite to the leg bearing the weight of the body sinks down in walking—shortening the limb, flattening of the buttocks, etc. The trochanter stands above Nélaton's line, and the head can be felt backward among the gluteal muscles. The prognosis for untreated cases is bad, as nearly all complain, later in life, of pain on walking or standing and even inability to walk. Every case treated between the ages of 4 and 10 years can be cured (freed) of the dislocation by one means or another. The safest, quickest and best method is the "bloodless reduction" of Lorenz. The most suitable age is between 4 and 8 years. The adductor muscles are torn by forcible abduction. Then the thigh is flexed, and extension made in a vertical direction with the hand or a wedge pressing on the trochanter from behind. When the head comes forward to the level of the acetabulum the leg is abducted, pressure on the trochanter being increased, when with a palpable and audible snap the head suddenly pops "over the posterior rim" of the acetabulum. The reduction can also be affected "over the upper rim" with extension made by two assistants pulling on a skein slung around the thigh. Traction by means of a screw has been given up, on account of the danger of fracture to the collum femoris. The reduced leg is placed in plaster of paris in the position of flexion, extreme abduction and slight inward rotation of the foot for four to six months. A high shoe is placed under the reduced leg to permit the patient's walking about. "Functional burdening" of this leg causes the acetabulum to become deepened, and after six months the joint is quite stable. The leg is again fixed for three months in a medium position. Then the patient is given a slightly higher shoe under the sound foot, to abduct the reduced side slightly, and gymnastics and massage complete the cure. Lorenz reports but 10 per cent. of total failures. If this fails the joint can be opened and the bloody reduction of Hoffa, in which the acetabulum is scooped out with a Volkmann spoon, performed Should this fail, resection of the head, with bony ankylosis, will give the patient a useful joint.

Dr. William E. Wirt, in discussing the paper, said that he thought the author was a little too enthusiastic in regard to the results to be obtained by the Lorenz method. He quoted a report made by Whitman showing that, while the method secured reduction, it did little toward relieving the lameness. In a certain number of cases the bloodless method is the best. One advantage of the bloodless method is that it does no harm to the patient. He reported a case of his own in which he had tried the bloodless method and placed a plaster cast on the limb. While away for a few months another physician removed the cast and pronounced the result a cure. Within a week dislocation recurred and the work had to be done over again. Fixation must be maintained for a long time in order to obtain a cure. He showed a brace which he had used to maintain the limb in position after the cast had been removed. He said that it required a good deal of force to reduce the dislocation by the bloodless method, and that the force has to be continued for a considerable length of time.

Dr. Walter G. Stern, in closing said that if a case was taken in time it could be cured by the Lorenz method. In case of failure at the first trial, a second or third may succeed. Finally, the bloody method can be tried. The advantage of the Lorenz method is that while the results may not be perfect, yet it does secure a stable limb. He had seen 220 cases in Lorenz's clinic in which there occurred only three fractures of the femur. These fractures occurred in cases of great deformity in which several sets of assistants were tired out in pulling for extension. Lorenz uses assistants for this purpose, and has discarded all screw devices.

PRESENTATION OF SPECIMENS.

Dr. Augustus F. House presented specimens of adenoma of the thyroid gland. He had removed nine during the last six months, and had operated by making a long, circular incision around the base of the neck and turning back a large flap of skin over the tumor. In this way the scar is where it will not be seen, and keloid is not so likely to follow. In the cases which were anemic he had put from one to two quarts of saline solution into one of the veins in the neck. None of the operations were done under local anesthesia.

ALBUMINURIA WITHOUT NEPHRITIS.

Dr. P. Maxwell Foshay reported a case in which albumin had been detected over a year ago and at the present time there is still a trace to be found. The chief point of interest is that at the end of fifteen months there are no casts or other foreign elements in the urine. There is no change in the vascular system, and no symptom of systemic disease. The patient is a young man, and the albumin had been found in an examination for life insurance. Careful search failed to reveal any cause for the albuminuria. While many such cases entirely recover, and while prognosis in the average is good, yet they are not safe risks for life insurance, because we can not yet distinguish between those cases which subsequently develop nephritis and those which do not. Therefore, in the present state of our knowledge, such cases have to be refused life insurance.

Dr. Henry W. Rogers had seen a similar case, which, at the end of two years, developed a true nephritis. He said that the arteries should be carefully examined as well as the urine.

AORTIC ANEURYSM.

Dr. Frederick C. Herrick showed a specimen of a small aortic aneurysm and complete aortic insufficiency. The heart was very large, weighing 828 grains, and the ventricular walls, especially the left, were very much hypertrophied. There was absolutely no aortic closure when the case was studied before death. Several times there had been a pulsus bigeminus and pulsus alterans. The area of dulness was very large, but there was no aneurysmal bruit.

Dr. W. T. Howard said that he had reason to think that aneurysm was very common in Cleveland and vicinity. He had seen many more cases since he came here than he had in Baltimore. Aneurysm of the aorta is not the cause of hypertrophy in the left ventricle. Dilatation of the aorta does not increase the vascular tension, nor cause cardiac hypertrophy.

Toronto Clinical Society.

Stated Meeting, held November 14, 1900.

POST-HEMIPLEGIC MOTOR APHASIA.

Dr. W. H. Papler presented a man aged 43, who in 1891 had severe headaches lasting for a couple of weeks and followed by weakness of the right arm and leg with some difficulty of speech. From this he gradually improved. Two years thereafter he had another attack, at which time he remained in the hospital perfectly insensible for three weeks. He regained consciousness and left; there was no paralysis at that time. About six months after that he had a series of attacks of temporary insanity lasting from two days to two weeks at a time and six to eight months elapsing between the attacks. He is now the subject of these attacks. During them he can not speak voluntarily nor answer any questions. He can not repeat words and can not read aloud nor write. In most of the attacks he uses oaths and unintelligible gibberish. The attacks are now very frequent, varying from one to eight in twenty-four hours and lasting a minute or less. There is no paralysis remaining now, but there is slight rigidity of the right leg and walking is defective. Dr. Papler considers that there was originally a hemorrhage or a thrombus in the middle cerebral with serious injury to the posterior part of the third left frontal convolution. The patient has been taking a dram of potassium iodid three times a day.

TRAUMATIC PARALYSIS OF THE RIGHT RECURRENT LARYNGEAL NERVE.

Dr. H. E. Tremayne, Lambton Mills, presented a boy of 14 years, who about ten weeks before, while going up a hoist, lying on the floor looking downward, had received a jam in the neck between the floor of the hoist and the floor above. He was seen by the Doctor a few minutes afterward, and complained of very severe pain on the slightest movement of the neck. His voice was very hoarse and there was a puffiness at the root of the right sternomastoid; but the skin was not broken anywhere. About November 7 he was again seen by the Doctor, when he complained of cough, which caused him to vomit up his food. Examination of the throat revealed the right cord immovable.

TUBERCULAR TUBES, WITH ACUTE PERITONEAL INFECTION.

Dr. H. A. Bruce read a history of this case and presented the specimens. It occurred in a young woman of 26 years, who had always been healthy and had been accustomed to heavy domestic work. Five weeks ago she suddenly was taken with severe pain in the abdomen and vomiting, with temperature, 102, and pulse 110. Her abdomen rapidly filled with fluid. There was no evidence of disease in the lungs, kidney or bladder. Her uterus was found fixed with a fulness on either side. On opening the abdomen, it was found filled with a dark greenish fluid of which several quarts were removed. The tubes were of the size of a small banana, the peritoneal surfaces soft and red, and looking like granulation tissue. They were removed, and the patient made a good recovery. It is now five months since she left the hospital and she continues in good health. Microscopic examination revealed tubercle.

ALOPECIA UNIVERSALIS.

Dr. Graham Chambers presented a female of 20 years; she said that her hair began to fall out in patches when she was about 5 years of age, from which she subsequently fully recovered. At the age of 12 she again began to suffer in patches, and since that date has never been free from the disease. At the present time she has no hairs on the body with the single exception of two small fine hairs on the anterior portion of the scalp. In 1898 she was treated for interstitial keratitis.

ATAXIC PARAPLEGIA.

Dr. Graham Chambers presented a girl of 17 years, with a negative family history. Menstruation began at 14, but since has been very irregular. In March last the cellar of the house where the patient was working was flooded, and not knowing that she was menstruating at the time, she took off her shoes and stockings and waded through the water, which came up to her knees. Two days later she complained of feeling tired and that her left leg was so heavy she could not lift it. A month later the disease extended to the right leg, with numbness and heaviness, but she suffered no pain in the legs or back. Both ankle and knee clonus are present in the left leg. Romberg's sign is present; and the patient can not distinguish hot from cold on the plantar surfaces of the feet and on the sides of the ankle-joints. Several patches of skin between the ankles and the knees are anesthetic. Patient is now unable to walk without aid.

HYDATID CYST OF THE PANCREAS.

Dr. George A. Peters reported this case, which occurred in the practice of Dr. MacKinnon, of Guelph, and on which Dr. Peters had been asked to operate. It occurred in a young man of 20 years of age, of Spanish birth, a resident of the Argentine Republic, who was on a short sojourn in Ontario. In May, 1900, he came under the care of Dr. MacKinnon. For two or three years the patient has suffered from attacks of pain obscurely located in the stomach and bowels, and latterly had his appendix removed, at which time a tumor could be felt in the left hypochondriac region, which at times was the seat of great pain. The cyst was first aspirated, and thirty ounces of a limpid fluid of sp. gr. 1.13 withdrawn. Much relief was experienced, but the cyst slowly filled, and the temperature and pulse showing that septic process was proceeding, it was decided to operate. On examination, a rounded tumor could be felt below the ribs on the left side, about midway between the nipple and sternal lines. Its relation to the pancreas was determined by the stomach resonance above the tumor and between it and the liver as well. Between the spleen, kidney and tumor, resonance was also present. The operation was done from behind, the incision being made along the margin of the erector spinæ, three inches long. Considerable difficulty was experienced in its removal, owing to the toughness of its walls. An examination of the fluid shows numerous daughter cysts with their attached embryos as well as many separate hooklets. The specimens were exhibited by Dr. Peters, and the hooklets were well seen under the microscope. A search of the literature so far by Dr. Peters reveals no other reported case of hydatid cyst of the pancreas.

Therapeutics.

Phenosalyl in Laryngeal Tuberculosis.

Dr. S. von Stein, in *N. Y. Med. Journal*, states that phenosalyl is a bactericide which ranks next to mercury bichlorid in efficiency. He has used it in sixteen cases of laryngeal tuberculosis with marked results, always applying a local anesthetic first. Phenosalyl is composed of:

Acidum carbolicum	9 parts
Acidum salicylicum	1 part
Acidum lacticum	2 parts
Menthol	1/10 part

He claims that under this treatment dysphagia has improved, limited or diffuse infiltrations have become smaller, and improvement when ulceration is present combined with infiltration. The dyspnea, expectoration and bacilli were reduced. He regards his treatment as positively curative.

Acute Capillary Bronchitis.

The following mixture has been recommended by Whitla, in the "Manual of Therapeutics:"

℞.	Vini antimonialis		
	Spiritus chloroformi, āā	ʒiv	16
	Spiritus ammoniæ arom	℥i	32
	Liquoris ammonii acetatis	℥ii	64
	Aquæ q. s. ad	℥viii	256

M. Sig. A tablespoonful every two hours.

Treatment of Postpartum Hemorrhage.

Dr. Byers, of Belfast, in the *Amer. Jour. of Obstetrics*, advocates the following treatment for hemorrhage from relaxed uterus, which should be resorted to in the order named:

1. External uterine massage.
2. Irrigations of the uterus with hot saline solution.
3. Introduction of the hand into the uterus.
4. In case of failure of the first three, bimanual compression of the uterus.
5. Gauze plugging the uterus.
6. The drawing downward of the uterus.
7. If hemorrhage comes from the lacerations of the genital tract, it is recommended to stitch if you can, and plug if you can not.

Dr. James H. Etheridge, former professor of obstetrics, Rush Medical College, always insisted on making pressure on the abdominal aorta in severe postpartum hemorrhages.

Abortive Treatment of Boils.

Dr. Jorissene, a French physician, states that a good application for aborting boils consists of:

℞.	Hydrarg. oxidi rubri	ʒi	4
	Lanolini	ʒx	40

M. Sig. To be rubbed in well once a day, or oftener on large ones. Acne and whitlow can be subjected to the same treatment.

—*Pract. Revue.*

Nerve Tonic.

As a tonic in functional nervous diseases Dr. Julius Flesch gives the following combination and states that he has obtained excellent results from its use:

℞.	Quininæ ferrocitratis	gr. xlv	3	
	Strychninæ nitratis	gr. i		06
	Extracti kola fluidi			
	Sodii glycerophosphati āā	ʒvi	24	
Dissolve slowly by heat and add:				
	Syrupi aurantii	℥vi	192	

M. Sig. One teaspoonful after each meal.

—*N. Y. Med. Jour.*

Treatment of Thrush in Infants.

Escherich suggests a small pledget of sterile cotton thoroughly impregnated with about three grains of finely pulverized boric acid to which a little saccharin has been added. The pledget is then placed in a little bag made of silk and given to the child to suck. The saccharin being pleasant, the child is quite willing to retain the bag in the mouth, so the boric acid acts constantly on the parasite. A new sac is used each day. Cure is said to be prompt. —*Phila. Med. Jour.*

Treatment of Croup.

The following outline for the treatment of croup was published by De Guy in *Jour. des Practiciens.* He states that aside from the use of antitoxin, it is wise in many cases to use local antiseptics.

As a disinfectant, if the breath is fetid and the throat is sore the following is advised:

℞. Chloral hydratis	ʒi-ii	4-8
Aquæ destil	Oii	1024

M. Sig. Use with a soft catheter as a wash for the postnasal spaces and pharynx, the child being held in such a position that the head is below the body; or:

℞. Potassii permangan	gr. iv	25
Aquæ—boiled	Oii	1024

M. Sig. To be used the same as the above.

Hydrogen peroxid in the proportion of one to ten may be used for similar purposes. These washings of the postnasal spaces are continued as long as necessary to overcome the fetor and to combat the development of the false membrane or until the membrane has disappeared, in order that the Loeffler bacillus may be destroyed.

TO OVERCOME THE DEPRESSION.

For the purpose of overcoming the depression, which is frequently pronounced, the following is given as a rectal injection:

℞. Caffeinæ		
Sodii benzoatis, āā	gr. x	66
Aquæ destil	℥ss	16

M. Sig. Per rectum once or twice daily.

CARDIAC TONIC.

As a cardiac tonic by the mouth the following is recommended:

℞. Caffeinæ	ʒi	4
Tinct. kolæ	ʒvi	24
Ext. cinchonæ fluidi	ʒiii	12
Vini	Oii	1024

M. Sig. Take a wineglassful several times a day.

Artificial serum may be injected in quantities varying from two to ten ounces where caffein is not sufficiently stimulating. The serum is composed as follows:

℞. Sodii chloridi	ʒii	8
Sodii sulphatis	gr. xlv	3
Aquæ destil	Oii	1024

M. Sig. By hypodermoclysis.

TO CONTROL NERVOUS EXCITATION.

The nervous excitation may be controlled by the following:

R. Sodii bromidi	ʒi	4
Antipyrini	ʒii	8
Aquæ menthæ pip	℥ii	64
Syr. aurantii	℥iv	128

M. Sig. A teaspoonful, according to age every few hours.

De Guy states that sodium benzoate is a valuable remedy in case bronchitis should develop:

℞. Sodii benzoatis		
Aq. laurocerosi, āā	ʒii	8
Syr. aurantii		
Aq. menthæ pip., āā	℥viii	256

M. Sig. One teaspoonful two or three times a day.

DEODORIZER.

As a spray, to be used in the atomizer for the purpose of deodorizing the atmosphere of the room:

R. Eucalyptol		
Essentiæ thymi		
Essentiæ citron		
Essentiæ lavendulæ, āā	ʒi	4
Alcoholis	℥v	160

M. Sig. As a spray, to be used in the room.

Spasmodic Croup.

℞. Ammon. carb.	gr. ii	12
Syr. senegæ	m. x	66
Mucilag. acaciæ	ʒii	8

M. Sig. One such dose to be given every two hours, unless patient vomits; if vomiting occurs diminish the dose.

AS A SPRAY.

Also in a steam atomizer:

℞. Sodii carbonatis	ʒi-ʒii	4-8
Aquæ q. s. ad	℥iv	128

M. Sig. Use every half hour. —Wharton.

IN TABLET FORM.

R. Ext. cannabis indicæ	gr. 1/20	003
Ext. hyoscyami	gr. 1/16	004
Tinct. opii camphoratæ	m. v	33
Syrupi ipecacuanhæ	m. x	66
Ext. glycyrrhizæ	gr. ii	12

M. Ft. compressed tablet No. i. Sig. One such dissolved in water every twenty minutes.

R. Chloralis hydratis	gr. lxxv	5
Potassii bromidi	gr. xlv	3
Ammonii bromidi	ʒss	2
Aquæ cinnamomi	℥ii	64

M. Sig. A teaspoonful in water and repeat in twenty minutes. —Holt.

CALOMEL FUMIGATION.

Holt states that, leaving out antitoxin and surgical operation, the only therapeutic measure that can be said to be of much avail in treatment of membranous croup is calomel fumigations. He does not regard it as a substitute for antitoxin but is beneficial where circumstances make the use of antitoxin impossible.

In giving calomel fumigations the child should be placed in a closed tent either in a sitting posture or lying down. In emergency cases a very simple arrangement, according to Holt, can be constructed by taking a piece of tin two inches wide and ten inches long and placing it over an alcohol lamp so that the flame will come close to the tin. The lamp is lighted and placed beneath the tent. Place ten or fifteen grains of calomel on the plate and allow it to vaporize for ten to twenty minutes, and repeat every one, two, or three hours, according to the severity of the case, being careful not to have the fumes too concentrated.

Orthoform in Toothache.

Hildebrand, in *Ther. Monatsch.*, states that orthoform instantly and completely relieves severe pain due to inflammation of the pulp in decayed teeth. It should be applied in alcoholic solution on absorbent cotton.

Tinea Tonsurans (Barbers' Itch).

The *Jour. of Med. and Science* publishes the following formula, recommended by Dr. Hodara, of Constantinople, for treating barbers' itch:

℞. Sulphuris	ʒiiss	10
Zinci oxidi	ʒv	20
Sacchari	ʒv	20
Glycerini	ʒiiss	10
Lanolin		
Vaselini, āā	ʒv	20

M. Sig. Apply in thick layer night and morning until the crusts have been removed, then once a day.

Pleurisy.

The following mixture has been suggested by Matas to relieve the cough and remove the serofibrinous exudation:

℞. Ammon. carb.	ʒss	2
Aquæ laurocerasi	℥ss	16
Syrupi lactucarii		
Syrupi senegæ āā	℥i	32
Syrupi tolutani q. s. ad	℥iv	128

M. Ft. mistura. Sig. One tablespoonful every two hours.

Medicolegal.

Disregarding All Medical Testimony in Case.—Where it appears, in a personal injury case, that the jury, in reaching its result, must have disregarded the whole range of the medical testimony of the plaintiff or defendant, notwithstanding the credibility of the witnesses stands unimpeached, and that their testimony can be reconciled with the other evidence in the cause, this of itself, the Supreme Court of New Jersey holds, in Barry vs. Pennsylvania Railroad Company, is ground for a new trial.

Waiver of Privilege in Action for Services.—Waiver of privilege as to one or more of several attending or consulting physicians, the fourth appellate division of the Supreme Court of New York holds, in the case of Hennesy vs. Kelly, is *not* a waiver as to all, as held in the decision reported on page 451 of THE JOURNAL of August 18, 1900. In particular, it holds that as to two physicians called in consultation at different times there was a waiver of privilege as to the one because the patient had given evidence as to the occasion when he was present, and as to which he testified, but that the evidence of the other was not admissible because no evidence with reference to the occasion he was present had been given by the patient.

May Show Condition of Womb and Probable Sterility.—If a married woman is injured by the negligent act of another, she is entitled, the Court of Appeals of Kentucky holds, in the case of the South Covington and Cincinnati Street Railway Company vs. Bolt, to maintain an action for damages, and the same criterion of recovery exists as to her as to a man or a single woman. Moreover, it holds that the married woman injured in this case was entitled to show by the physician who attended her the condition of her womb, and that in his opinion she could never again bear a child, although, as the judge properly instructed the jury, the jury could not consider the question of her sterility in fixing damages. The court says that she was entitled to show the extent of her injuries, and in describing the condition of the womb, if it showed that she would probably be sterile thereafter, it was proper for it to go to the jury. It was her right to show the extent of her injuries, but, if a certain condition which appeared to exist could not enter as an element of the question of damages, it was proper for the court to tell the jury so, but the necessity for doing that could not deprive her of her right to show the extent of her injuries.

Validation of Imperfect Registration Not Retroactive.—Section 148 of Chapter 661 of the New York Laws of 1893 pertaining to the public health and regulating the registration and licensing of physicians and surgeons provides that, if there has been an "imperfect registration" through some technical or unintentional omission, the board of regents may, in the manner therein prescribed, "make valid the previous imperfect registration." But this provision, the fourth appellate division of the Supreme Court of New York holds, in the case of Ottaway vs. Lowden, is not retroactive in effect. This was an action to recover for medical services. When the services were rendered the plaintiff possessed no license, and had no authority to prosecute his calling. He claimed that his imperfect registration from his failure to get his diploma from a medical school in another state properly indorsed had been validated under said Section 148. This validation, however, occurred after the services in question were rendered, and the court holds it insufficient, not being retroactive, to authorize the maintenance of this action. It says that the state board cannot endue one with a cause of action where none existed before. It may do away with the necessity of any further license or registration by injecting life into papers already filed, and give one a "clean bill of health" for the future; but that under this act is the extent of its authority. This interpretation, the court admits, may operate as an injustice in a particular case, but the statutes, it goes on to say, are a safeguard both to the public and those engaging in the practice of physic and surgery, and should be rigorously enforced. During the time the services in question were rendered the plaintiff was liable to indictment and conviction for practicing physic and surgery without proper warrant. If this act were to be given a retroactive effect, there would be the anomalous condition of affairs whereby he could recover for services the rendition of which by him constituted a crime. There is no warrant in the law for the state board to determine that he in fact during all this period was licensed to practice.

Postponement of Marriage for Venereal Disease.—The principal question before the Supreme Court of Missouri,, Division No. 1, in the breach of promise case of Trammel vs. Vaughan, was whether the defendant had a right to postpone marriage with the plaintiff upon the appearance between the date of the contract and the date for its performance, apparently without his fault at that time, of what he denominated a loathsome venereal and contagious disease; in other words, stated broadly, whether the defendant would have been justified in marrying the plaintiff, even with her consent, while he had the disease. Of course, the court says, if the defendant entered into the contract knowing of such an impediment to its consummation as a disease rendering it unsafe or improper for him to marry, it would be an aggravation of the plantiff's damages, and she would be entitled to refuse to marry him, and to treat his condition as a breach of the contract—a fraud perpetrated upon her. But, if the thing to be performed becomes unlawful, without his intervening fault, after the contract is entered into, the performance is excused by force of law. So, the court finds that, while there are few reported precedents for the conditions presented in this case, it has been held that if a party to a marriage contract develops a disease which renders it unsafe or improper for him to marry, without intervening fault on his part, between the date of the contract and the date appointed for the marriage, he is entitled to have the ceremony postponed until the result of the disease is known or he is cured. It also points out that marriage is not merely a civil contract, but one to which the state is a party and has an interest in, and one which implies that the contracting parties know of no legal or physical impediment to the contractual relation and its consequences. Then, it says that willfully to communicate a venereal disease is clearly cruelty, and is a ground for divorce, whether specifically enumerated in the statutory causes for divorce or not. It recalls, too, that it has been stated that intercourse with a woman, though she was willing thereto, by a man who was infected with a venereal disease, would constitute the act a common assault, for the fraud would vitiate the consent. Now, if these principles be correct, it must also be true, the court holds, that it is legally as well as morally wrong for a man, while infected with such a disease, to marry; and a man, for such cause, is entitled to demand a postponement of the marriage until he is cured. The idea that the ceremony should be performed, and the consummation of the marriage postponed until he is cured, it continues, is not only intolerable, but obnoxious to a proper subservience of the public interests and morals. This, too, whether the woman knows his condition, and consents to such an arrangement, or not; for, though she may be willing to waive the defect, or be indifferent to the condition or its consequences to her and her children, the third party to the contract, the state, has a right to and does object. If the disease is of a temporary character, and can be easily cured, the defendant is entitled to postpone the marriage until he is cured; and, if the disease is of a permanent character, he is not only entitled to refuse to carry out the contract, but it is his duty to do so.

AMERICAN.

1. **Supracondyloid Fracture of the Humerus.**—The prognosis of these fractures heretofore has been bad as regards motion of the joint, and Shands gives his views on the improved methods of treatment. The most important point is knowledge of the position of the fragments, and the X-ray offers us this. His method is to drill holes through the fragments and suture them in position with kangaroo tendon, excepting in cases where the fracture is oblique, where he uses a drill long enough to project through the dressing, until the end of the second week, perfect asepsis being employed. His experience and observation convinced him that this method is the correct one and the sooner it is generally adopted the fewer stiff and deformed elbows we shall meet with. He reports three cases, illustrated by skiagrams.

3. **Kyphosis.**—The apparatus here described by Forbes is practically a lever whose lower extremity is the fulcrum and upper extremity the power, but the resistance is at the kyphosis. This can be made to exert pressure at the fulcrum or at the point of kyphosis and thus tend to draw the diseased bodies of the vertebræ apart and extend the whole vertebral column above that point, transferring the superimposed weight of the bodies to the transverse processes of the vertebræ and thus reduce the kyphosis. In addition it will perfectly immobilize the vertebral column and by preventing attrition place the parts in the most favorable position for the arrest of the diseased process. The methods of its employment are given and the author states in detail what he considers to be its advantages.

4. **Recrudescing Angina.**—From a study of several cases, together with those he has found in the literature, Mayer arrives at the following conclusions: 1. That anginas due to the bacillus of Friedländer may exist in a subacute or chronic form. 2. They occasion no distress, except perhaps in the beginning of the membranous deposit. 3. They may appear in membranous form, exfoliating and recurring. 4. In the chronic form treatment seems to be of no avail, the bacilli eventually becoming much less active, and the condition ceases by limitation. 5. They are probably much more frequent than the few recorded cases seem to indicate.

5. **Intraspinal Cocainization.**—Goldan reports experience and operations of this method from the standpoint of the anesthetist. He thinks more fluid, if anything, is injected than is lost by the puncture. He sees no special advantage in obstetrics over chloroform, and thinks that it has been used needlessly in many minor cases. He notices inconvenient effects and warns against puncture of the spinal cord, which he thinks may be dangerous, and an accident of this sort should be carefully avoided. The symptom of shock is very pronounced in these cases and its intensity can only be compared with profound chloroformization. He sees no advantage in the matter of speed in the operation, and many disadvantages, and asks in conclusion whether the use of the method may not be a step backward rather than forward.

6. **Empyema in Children.**—Wachenheim reviews the special signs of this condition in children, the chronicity, the temperature curve, rapid feeble pulse, percussion and ausculta-

tion signs, and remarks that the ordinary physical methods are more or less unreliable in young children and we never can feel certain of our diagnosis after employing them alone. The most important recourse is exploratory puncture, and he considers the risks of this very slight. The danger of puncture of the lung is, he believes, imaginary.

8. **Uterine Fibroids.**—The questions specially noticed by Richardson are: Need of thorough *preliminary examination*; the condition of the kidneys; difficulties of palpation upon a conscious patient; the importance of vaginal examination before operating, which can be made aseptic if care is taken; the element of time in the operation and the need of speed and yet caution; avoidance of anything like carelessness or undue speed where caution is required; the recognition of the intestines and other organs; the condition of the ureters, the choice of operation between hysterectomy and myomectomy with special reference to the future of the patient. The technique of the operation of myomectomy is described too fully to be here reproduced.

9. **Hot-Water Immersion in Puerperal Eclampsia.**—The general principles on which eclampsia should be treated are attention to the conditions of toxemia, maintenance of stable nervous equilibrium, due elimination by other organs as well as kidneys, and Green advises an exclusive milk diet when the kidney is at fault, diaphoresis and cutaneous stimulation by heat. The hot-air bath is most appropriately used in the treatment of actual eclampsia, as the patient is then comatose and unable to help herself, and hot-water immersion is impracticable. The hot-water pack is often effective, but when circumstances permit, the hot-water immersion bath is most satisfactory. It not only causes profuse diaphoresis and reduces blood tension, but is a nervous sedative itself. The water should be as warm as can be borne. The patient should remain in it until profuse perspiration of the face shows that the sweat glands are in full activity, and friction with the flesh brush is also advisable. When free perspiration has been induced the patient should be rolled in a blanket, placed in a warm bed and covered with several blankets, and perhaps a rubber sheet. It should be remembered, however, that a hot bath is a powerful agent in the induction of labor. It should not be used unless labor is imminent. There should be an ample ingestion of liquids with free diaphoresis. The paper concludes with a report of three cases of this treatment with benefit.

10. **Diphtheria Antitoxin.**—McCollom's article shows the effect of the antitoxin treatment in several cities, the ratio of morbidity from diphtheria in Boston and the percentage of mortality by age in London and in Boston. His conclusions from the observations of nearly 8000 cases are as follows: 1. That the ratio of mortality of diphtheria per 10,000 of the living was very high in Boston previous to 1895. 2. That the ratio of mortality per 10,000 has been very materially reduced since the introduction of antitoxin. 3. That the percentage of mortality in the South department is lower than that of any of the hospitals taken for comparison. 4. That since larger doses of antitoxin have been given the death-rate has been materially reduced, this reduction having occurred in the apparently moribund cases. 5. That no injurious effect has followed the use of the serum. 6. That to arrive at the most satisfactory results in the treatment of diphtheria, antitoxin should be given at the earliest possible moment in the course of the disease.

12. **Calculi.**—Leonard argues for the Roentgen rays in detecting calculi, especially in the kidneys, ureters and bladder, and while detection of vesical calculus is generally easy by the ordinary methods, there are applications of this method that are especially useful. He thinks that the perfection of the technique will render this method still more valuable in diagnosis.

14. **Zoologic Names.**—The use and abuse of zoological names by physicians are dwelt upon by Stiles, who, while he does not claim that all physicians should be familiar with the rules of zoological nomenclature, believes that they generally take too many liberties with it; for example, the hydatid echinococcus is suffering from not less than sixty names, and the unarmed tapeworm has about forty names. He protests also against the changing of the spelling of zoological terms. This may seem trifling to the physician, but it is of importance for scientific accuracy when speaking of zoological subjects. For example, *tænia* may be another animal from tenia, and tinea is zoologically a moth and not a parasitic worm, nor is there any possible zoologic ground for the use of the term ameba. He concludes his paper with the following thesis: It is incumbent upon physicians to follow zoological customs in dealing with zoological subjects, as it is incumbent upon zoologists to govern themselves by the code of medical ethics in dealing with medical cases.

21. **The Neuron Doctrine.**—Allen concludes his article with the general statement of the findings of Golgi's method and the very apparent separation of the neuron units one from another. He says it seems to be no more proved that the Golgi and methylene-blue methods give deceptive results than do those of Apathy and Bethe, which have not had anything like so wide an application as the former, and more extended observations are required before we can throw overboard so favorable a hypothesis as the neuron doctrine. There is a *great deal of difference as to just what the neuron means* among authorities, and there are many who have not admitted an entire lack of continuity between the elements. Then if we should admit Apathy's view to be correct, it is not necessary for us to abandon the neuron. Its embryology is not affected. It may be necessary to modify our views somewhat, but the conception as a whole as a means of explaining certain facts is hardly to be given up.

22. **Medullary Narcosis in Obstetrics.**—Ehrenfest, after reviewing authorities, thinks that there is a possible future for the operation. If, however, we should be obliged to use instrumental delivery more often with it, it would seem a possible contraindication. As a substitute for other forms of narcosis it may be of value: if future work establishes the fact that these subarachnoidean injections are free from danger they may add some advantages in cases where heart failure, nephritis, etc., contraindicate the use of chloroform or ether. On the whole, however, it seems to be more than doubtful whether we are justified in recommending it as a substitute for light chloroform narcosis: the latter is always sufficient in the usual run of cases.

24. **Laryngeal Tuberculosis.**—Cohn would divide laryngeal tuberculosis into three stages: 1. Excepting circumscript infiltration or ulceration, the larynx is healthy. In this stage the treatment consists in curettage if infiltration be present and in cauterization with lactic acid if ulcer exists. If the general condition including the lungs be good, these procedures are imperative, and must be repeated at intervals of one to three weeks until the diseased tissue is completely removed. In the second stage, where extensive infiltration or ulceration exists we can not expect a complete cure and our main aim is to prevent secondary infection. The mildest method is by means of antiseptic inhalation; whether we use 1 to 3 per cent. carbolic acid, 2 to 4 per cent. boracic acid, or 1 to 2 per cent. lysol, is of no consequence. If the epiglottis permit an inspection of the larynx, the antiseptic swab is still better and a 10 to 30 per cent. solution of menthol in olive oil. If we see the case in its last pitiful stage all we can do is to treat it symptomatically. Administer a morphin powder before each meal, or better still, apply a 20 per cent. solution of cocain to the pharynx. In impending suffocation, tracheotomy, of course, is necessary. The general treatment corresponds closely to that of tuberculosis.

25. **Local Anesthesia in Hernia.**—Meyer thinks the advantages of this method of operating are slight as compared with the pain and discomfort produced. He does not wish to be understood as unqualifiedly condemning it, but wants to define its limitations. Its only real advantage is the removal of the element of danger of general anesthesia, and that very seriously limits its employment.

32. **Gall-Stones.**—The operation, here described by Kelly, is feeling for the gall-bladder through the lower incision of the abdomen, pressing out its contents and, if the stone is present, pressing it up against the abdominal wall and cutting down on it. The gall-bladder is drawn well up to the peritoneal incision and there is no danger of contamination with the bile. The pressure holds the tissues from below and keeps them anemic, and the skin, fat and muscle are separately divided. The peritoneum is easily recognized, and on reaching this layer a little nick is made and the two edges caught with mosquito forceps; as the peritoneal incision is made a little larger, the gall-bladder with the stone appears in the incision, is opened and its edges caught, as the incision is made large enough to evacuate its contents. The edges of the gall-bladder after the removal of the stone are united with fine silk sutures while held up by four of Halsted's delicate mosquito forceps, the suture beginning at one end of the incision and continuing to the other embracing all the coats but the mucosa. The same suture is then continued back to the starting-point as a quilted suture, burying the first layer when the ends are tied together. If the gall-bladder is normal he does not hesitate to drop it without a drain, but if it is diseased he closes with an interrupted suture and inserts a small drain provisionally. The abdominal wound is then closed and the operation complet within a few minutes of its commencement. Several cases are reported operated on in this manner, showing its advantages.

33. **Rheumatism.**—Stengel remarks, after studying the bacteriologic nature of rheumatism, that it is important to recognize several fundamental facts as regards treatment: 1, the tendency in many cases towards spontaneous recovery; 2, complications, such as endocarditis, pleurisy, pericarditis, etc., are frequent and more likely to occur in protracted cases than in those of short duration; 3, the complications are probably, as a rule, secondary to joint disease and not to the infective lesion—such as tonsillitis—that was the primary focus, consequently the severity of the local joint lesion bears a relation to the likelihood of the development of the complications. He states these facts as probable, not as absolutely proved. Of the drugs used in the treatment of rheumatism, the salicylates hold the first place, and if they are not specific in their action they at least relieve pain. He also mentions as another valuable method, fixation by splints of plaster, which he thinks is often the best method of producing rest for the parts. He has used the plaster cast considerably in gonorrheal and polyarticular types and thinks its beneficial effects are immediate. In polyarticular rheumatism it has been most useful when the knee, elbow and ankles have been affected. The wrists and smaller bones can be managed with splints and in other ways quite as satisfactorily. In some cases of rheumatism, where rebellious to treatment with the salicylates and rest and the general condition is unsatisfactory, tonics are advisable, and in a number of cases of this sort he has employed small doses of bichlorid of mercury with good result and attributes this to the tonic influence of the drug. It seems to be of value as a stimulant of hemogenesis or as a tonic, not as an antiseptic. Other tonics may be of use, such as iron; strychnia and the iodids are of undoubted value in some chronic cases. In conclusion, he mentions the serum treatment, and he has made a few trials of antistreptococcic serum in cases of obstinate rheumatism in which improvement soon followed the injection. The dose was one-third the customary amount employed in streptococcic infection and the remedy was administered every other day for a week or more, when ordinary treatment was resumed. While conclusions would be rash from this limited experience, he thinks the method deserves further trial.

34.—See abstract in THE JOURNAL, XXXV, p. 1105.

35. **Surgery of the Gasserian Ganglion.**—Neff notices the history of the operations on the Gasserian ganglion and the methods, and concludes his article as follows: 1. Trigeminal neuralgia is an ascending neuritis, peripheral in origin. The second and third branches, rather than the first, are the ones most likely to be involved. 2. If the disease persists after several months' trial with drugs, electricity, etc., surgical intervention is indicated. 3. If only one branch is involved and the disease is not of long standing, as much as possible of the affected branch should be removed with a view of relieving pain and preventing the upward progress of the disease. 4. If more than one branch is involved, and the pain is severe and has persisted for a long time, the ganglion should be extirpated, all other means having failed. 5. The temporal route should be followed, the Hartley-Krause, or preferably, Cushing's modification of it, being the most rational procedure. 6. Pain will not recur with original severity in more than 1 or 2 per cent. of the cases operated on, or in any degree in more than 4 or 5 per cent., and is invariably due to an incomplete operation. 7. It is important to remove the ganglion and its branches intact in order to be certain of the completeness of the operation and to insure a careful and thorough microscopic examination of the specimen. 8. The present mortality is about 10 per cent. Increased experience and an improved technique will undoubtedly diminish this mortality, and dissipate the risks of this hitherto most formidable, difficult and dangerous operation.

38. **Post-Mortem Examinations.**—The paper by Haines insists on the importance of thorough work in the post-mortem; we must look always for everything that exists. He notices particularly the staining of the body as indicating the positions in which it has laid, as it often happens that the body has been removed before seen by the physician. The subjects of atheromatous change are especially prone to early, rapid and extensive post-mortem staining and he attaches great value to this, and mentions cases to show that it may appear even before death. Other points mentioned are the conditions of the mucous membrane of the mouth, which are of value but sometimes deceptive, post-mortem rigidity, insufflation of lungs, post-mortem vesicles, and the need of examining the pharynx and larynx for obstruction. He says the post-mortem room is the sarcophagus of snap diagnoses, the abode of disappointed expectations, but a Mecca to him who will improve his knowledge.

40. **Pathogenesis of Gall-Stones.**—Summa offers the following conclusions of his article: 1. The causation of gall-stones is a very manifold one. The sooner we abandon the natural desire to search for an etiology common to all gall-stones the sooner we shall approach the truth. 2. The formation of gall-stones requires a union of at least two factors. 3. Notwithstanding all the efforts made thus far, there are still a number of etiologic factors unknown to us. 4. Our knowledge of the chemical changes in the bile and of the anatomic changes in the gall-bladder in various, particularly febrile, diseases should be enlarged. 5. One, and surely a very important, group of gall-stones is apparently due to the combined effect of temporary impediments in the outflow of bile and lithogenic catarrh of the biliary system. The chief material of these gall-stones, cholesterin and lime salts, is not derived from the bile, but from the destruction of the epithelial cells of the mucosa. 6. Such gall-stones deserve their name "gall-stone" only on account of the locality they are found in. 7. Upon the common sense the question forces itself, why do the same factors, temporary stasis and lithogenic catarrh in other places, as, for instance, salivary ducts, pancreas, pelvis of kidney and urinary bladder, not form similarly composed stones? He leaves the answer of this question to the unconditional admirers of Naunyn's theory.

43.—This article has appeared elsewhere. See THE JOURNAL, XXXV, p. 204.

45.—See abstract in THE JOURNAL, XXXV, p. 1050.

48. **Virginia Medical Laws.**—Martin discusses the medical laws of Virginia as compared with those of other states in relation to the question of reciprocity. He thinks the law *is not sufficiently enforced*, and he wrote a series of inquiries which he sent out to examining boards of twenty-five different states, and gives briefly the substance of these replies. In North Carolina there is no trouble apparently in having medical laws enforced. The profession and the laity alike are interested in their enforcement. In South Carolina the rever is the case. In Kentucky, Colorado, New York, New Ha

shire and Wisconsin the enforcement of law seems to be fairly easy and thorough. In West Virginia, Maryland, Pennsylvania, Connecticut, Massachusetts, Tennessee, Indiana, Mississippi, and to some extent in Iowa, there has been more or less difficulty, due either to popular and professional apathy on the subject or to the vagaries of the courts in regard to irregular pretenders in medicine. In some of these states, however, the condition is improving. In Virginia he finds that they do have trouble and the difficulty is largely in securing prosecution of irregular practitioners and in the coöperation of the profession. There are some men who fail before the board and go home and practice, and there is another class who never take the trouble to appear. The examining board of Virginia is undoubtedly thorough and fair in its methods, but with these conditions its functions are seriously limited. He thinks the profession needs to see to not only the enforcement of the present law, but as to possible legislation which may impair it.

54. **Fractured Clavicle.**—Henson describes an appliance rather too elaborate in its details to be reproduced here, which he claims renders the parts immobile and uses the scapula as a factor in the management of the outer fragment better than other methods heretofore in use. It is perfectly comfortable and never slips or gets displaced without interference on the part of the patient.

55. **Tests for Urine.**—Hoge mentions certain past fallacies in the ordinary test for sugar, such as the use of chloral or the excess of creatinin in the urine, both of which will reduce copper and give the same reducing color. Urobilin also, when in excess, will reduce copper. In the Moore or Heller test a small quantity of sugar, less than one grain per ounce, is not detected, and if the patient is taking rhubarb or senna the urine will give a dark-brown color or cast. Certain substances in the urine, such as urea, urates, uric acid, creatinin, indican, urobilin and arsenic, tannic acid, carbolic acid, gallic acid, camphor, copaiba, salicylates, turpentine, glycerin and some alkaloids when administered internally will produce more or less reduction of copper. The objections to the Bottger test are due to the presence of albumin, pigmentation, mucin and other substances containing sulphur, which need first to be removed. Roberts' fermentation test is the surest and freest from error. The only objection to it is the length of time required. He gives the tests for creatinin, urobilin and indican.

56.—See abstract in The Journal, xxxv, p. 1425.

60. **Splenic Enlargement in Infancy.**—Acute splenic tumor occurs in infants, as in adults, in connection with acute infectious disease, and the enlargement is proportionately greater than in later life. Splenic tumor is much more common in infancy, occurring not only under the same conditions as in adults, but in many others. Not only do we have it in combination with leukemia, liver cirrhosis and malaria, all rare in children, excepting the latter, but especially in connection with rickets and hereditary syphilis. Both of these are frequently associated with anemia, and cases are reported illustrating these facts. The enlarged spleens in children reported by Morse are of interest. They disappear rapidly with improvement of the condition. His experience with hereditary syphilis has not been sufficient to warrant any conclusions, but he thinks it also disappears in this condition under treatment.

61.—See abstract in The Journal, xxxv, p. 1425.

70. **Artificial Illumination.**—The various methods of lighting are described and criticised by Alleman, who finds that the present methods are very unsatisfactory and the arc light the worst of all. He suggests as an improvement the concealment of the light itself and its reflection on the ceiling of the room, thus producing a diffusion which simulates, as far as possible, the diffusion of daylight. If it is possible to sufficiently light the room in this way, reading can be done in all parts with less fatigue and damage to the sight. He thinks that when a single light is used for reading purposes the best plan is the use of a translucent shade. An insufficient reading light is less harmful than the extreme contrast of a bright light in a dark room.

84. **Nitrous Oxid Anesthesia.**—Galloway reports the results of fifty cases of the combined use of nitrous oxid and ether, the former being used as a preliminary in the anesthesia. He thinks the advantages of the method entitle it to more extended use. They are: 1. That they give rise in the majority of patients to no unpleasant sensations. 2. Time required to produce unconsciousness is 50 to 60 seconds in the majority of cases and the patient is ready for the operation in two to three minutes. 3. It requires less ether by from 2 to 4 ounces. 4. Recovery is more rapid after operation, on account of the smaller quantity of ether required. Nitrous oxid alone may be used for short operations. In very few of these cases does it produce any alarming cyanosis, and with care these symptoms, should they occur, will not be serious.

88. **Rectal Valves.**—This paper of Pennington covers in part the same subject as that of his article published in The Journal xxv, p. 1520.

89.—See The Journal, xxxv, p. 1476.

91. **Compound Fractures.**—Leigh emphasizes the following points in the treatment of compound fractures: 1, free opening of the wound; 2, removal of all useless torn tissues; 3, thorough disinfection; 4, good coaptation of bones; 5, loose closing of wound; 6, firm pressure dressing; 7, constitutional treatment. He believes that attention to these points, together with good nourishing food and plenty of it and plenty of fresh water, mild cathartics, and the use of lime, which he has given in the form of syrup lactophosphate of lime, to replace the bone cells, will give good results.

94. **Landry's Paralysis.**—Schwab reports a case of Landry's paralysis with post-mortem in which the nerve cells were found normal, or at least the slight variations can be explained by pre-agonal or post-mortem chromatolysis. There was an absence of degeneration in the cord, and of neuritis; there was no myelitic process of softening or purulent inflammation and no meningitis. The positive findings were limited to the blood-vessels and the perivascular lymph-spaces alone, and consisted in a tremendous vascular congestion, thinning of the vessel walls due to this increased pressure, and hemorrhage with escape of free blood into the nervous structure, and possible increase in the number of vessels. There were no inflammatory products and no demonstrable disease of the vessel walls other than the thinning mentioned. Schwab suggests that possibly these hemorrhages are artefacts due to mechanical obstruction of over-full vessels while making sections, but against this is the fact that some of them show evidence of long duration and the hemorrhages are too frequent, and occur independent of the plane in which the sections were cut. There are two theories, both of which only partially account for the symptoms and neither is satisfactory. According to the first, the symptoms might be due to the effect of pressure of the free blood on the nervous structure. The number of the hemorrhages and their distribution favor this idea as well as does their prevalence in the upper portion of the cord, but against it are the great number of hemorrhages of recent date and the absence of the effect of old hemorrhages, such as fibrin, blood crystals, pigmentation, etc. The second theory is that a toxic process produces in the cord a condition very similar to that of non-purulent encephalitis affecting the nerve-cells of the anterior horns, but in such a minute way that their morphologic appearance could not be regarded as differing from the normal. In other words they were functionally affected. The absence of neuritis or degeneration would appear to strengthen this view, and the fever and constitutional symptoms can also be explained by it. The origin of the toxic process he traces possibly to old tubercular foci in the lungs. While not doubting the possibility of the parenchymatous nature of the process in certain other cases, in his he holds the preliminary change must have been an interstitial one. His view is that Landry's paralysis is not a distinct clinical type, but that it is an ascending paralysis comprising a group of symptoms depending on the most varied causes and with the most varied pathology, so that the name is only of clinically descriptive value.

96. **Beri-Beri.**—Bondurant first alludes to the epidemic of beri-beri that occurred several years ago in the State Insane Hospital of Alabama, and a similar one that occurred in 1895 in the Arkansas State Hospital at Little Rock. He has inquired among practitioners to find out whether the disease has been observed in other communities, but satisfactory evidence appears to be lacking, the cases being generally alcoholic, post-typhoid, multiple neuritis, etc. Multiple neuritis in the form of beri-beri, however, is very common in Mobile among the sailors in ships touching at that port; the Norwegian sailors seem specially affected and the port is dreaded on that account. It is noteworthy, however, that the disease is unknown among the local inhabitants and that it occurs in vessels that have been previously infected.

97. **Converging Prisms.**—Duane reports experiments on the effect on the vision of the converging prisms, especially as regards the notions of size and distance, and from it finds that in the great majority of cases—23 out of 28—the effect of converging prisms was to make the distant object appear either smaller or more remote, both in 17 cases, in 2 smaller, but not more distant, in 4 more distant, but not smaller; 2 of these last, however, were only examined with homatropin. Both apparent recession and apparent diminution increased *pari passu* with the amount of convergence. In some the recession appeared to be the primary effect, noticeable even with prisms too weak to produce any diminution in the size of the object, and in all more marked than the diminution. In other cases the diminution was primary and in only one instance, and that a dubious one, was the distant object alleged to look nearer, and in no instance was it reported as appearing larger, though there was an apparent exception in this which was corrected by further investigation. In a few cases in which there was no effect produced on the apparent size or diminution of the object across the room the amount of convergence employed was usually small, and analogy with other cases would lead us to suppose that with stronger prisms a decided effect would be produced both upon the size and distance. The effect on the apparent size and distance of objects seen through the converging prisms was less pronounced in those who from the start used little accommodation. On the other hand, the converging seemed marked to those whose sight at first was blurred by the excessive accommodation employed and cleared up afterward through relaxation of accommodation. Objects, as soon as they became distinct by relaxation of accommodation, appeared small and distant. The addition of a concave glass clearing up the sight that was blurred by the overplus of accommodation, had no effect on the apparent size and distance produced by the prisms. The effect of homatropin pushed to the point of complete relaxation of accommodation was in some cases to make the object appear farther off, but no smaller. In one case it apparently prevented the recession and diminution that had existed before. In 2 cases recession and diminution were marked both with and without homatropin. In 14 cases out of the 16 examined, the effect of looking through converging prisms at an object near by—18 to 30 inches—was to make it appear smaller, even with a very weak prism. The diminution of size was more marked than that of distance. Near objects generally looked more remote, though sometimes they looked nearer than they really were. With strong prisms the recession may be very pronounced. In all of the 6 cases examined under homatropin the near object looked either farther off or smaller, or both, and the effect was usually decided. The explanation of these facts, Duane remarks, is rather difficult, though the indications are that the accommodation, or the relaxation of an unnaturally tense accommodation, is the prominent factor in their production. He is inclined to think this disturbance of normal relations between the accommodation and convergence brought about by the use of converging prisms is chiefly responsible for the diminution in size that most persons see in this way. The relaxation that is also noticed seems apparently due to the same cause, but is considerably influenced by the effects of contrast and perspective. The psychic element must not be ignored, and accurate description is not possible to every one.

104. **Medullary Anesthesia.**—La Place reports, with other cases, one of fracture of the elbow-joint, one of spontaneous resolution of a sarcomatous tumor, and two cases in which medullary anesthesia was employed. In one, an aged man, 2 c.c. were employed. Anesthesia extended to the nipples in thirteen minutes. In the other case, however, twelve different attempts were made to reach the spinal cord with the needle and in no instance was it possible to extract any cerebrospinal fluid. There was no difficulty in introducing the needle, but there seemed to be an anomaly in the patient in this regard, nothing but blood could be withdrawn. He thinks possibly there was an obliteration of the sac in that region, due to old syphilitic infection. The patient was subsequently operated on with ether. The case is of interest on account of the failure to reach the subarachnoid space.

119. **Fetal and Infantile Typhoid.**—The possibility of fetal typhoid is discussed by Morse, who reviews the literature of the subject and sums up in the following: 1. The typhoid bacillus can traverse the abnormal, and possibly the normal, placenta from mother to fetus. Other organisms may also pass in the same way. 2. Infection of the fetus results. Because of the direct entrance of the bacilli into the circulation intrauterine typhoid is from the first a general septicemia. For this reason, and possibly also because the intestines are not functionating, the classical lesions of intrauterine typhoid are wanting. 3. The fetus usually dies in utero, or at birth, as the result of the typhoid infection. 4. It may be born alive, but feeble and suffering from the infection. If so, death occurs in a few days without definite symptoms. 5. It is possible that the fetus may pass through the infection in utero and be born alive and well. There is, however, no proof that this happens. 6. Infection does not always occur. The pregnant woman does not necessarily transmit the disease to her child. As regards infantile typhoid, that is, typhoid occurring under 2 years, he sees no reason why it does not occur; the probability should be greater the second year than the first. Nevertheless the statistics show that this is very rare or is unrecognized when it occurs. To demonstrate if possible whether typhoid really exists or is confused with gastrointestinal disorders of infancy Thayer and he examined the blood of 50 cases for serum reaction, in the summer of 1898, and in only one obtained a positive reaction. While the series is too small for definite conclusions, it supports the theory of the rarity of infantile typhoid. He goes over the literature of this subject also and offers the following conclusions: Except for the lessened exposure in the first year through food, there seems no obvious reason why typhoid should be less frequent in infancy than in later life. Nevertheless, judging from the small number of cases reported, it is less frequent. It may be really less frequent or only apparently so because the disease is not recognized, being mistaken for other conditions. Bacteriologic examinations in a large series of autopsies on infants and the use of the Widal serum test in a large number of sick babies seem to offer the best means for determining both the frequency and the character of the disease at this age. The accuracy of the diagnosis in many of the earlier reported cases must be regarded as very doubtful, and hence no satisfactory conclusions can be drawn from them. Analyses of the more recent and certain cases seem to show that the symptoms of infantile typhoid are essentially the same as in adults, but that the course is shorter and the mortality greater. These conclusions may be inaccurate, however, as it is possible that they are based on the severe cases alone, the milder cases having escaped notice. The pathologic changes in the intestines are, as a rule, insignificant. The contrast between them and the severity of the general symptoms is striking. The probable explanation is that in the infant, as in the fetus, but to a less degree, the disease is a general rather than a local infection. As regards the serum reaction, he thinks that it occurs in the infant as in the adult. There are no data available regarding its presence or absence in fetal typhoid. As regards transmission through the placenta, he reviews the literature and finds that the agglutinating principle may be transmitted in some cases and in most, not at all. The simple explanation of its not

occurring is that the placenta acting as a filter prevents the passage of the agglutinating principle, but the data are insufficient as yet to prove any theories. The transmission of the agglutinating principle through the milk is also discussed, and his general conclusions on the subject of serum reaction are as follows: The serum reaction occurs in infantile as in adult typhoid. There are no data as to whether or not it occurs in fetal typhoid. The agglutinating power may or may not be present in the blood of infants born of women with typhoid. If present, it is transmitted from the mother to the child through the placenta. It is possible, however, that it may be formed in the child in response to toxins transmitted through the placenta. The agglutinating principle can pass through the normal placenta. Part of it, however, is arrested in the passage. Whether or not it is transmitted seems to depend on the strength of the agglutinating power in the maternal blood and in the length of time during which the placenta is exposed to it. It may be transmitted to the nursling through the milk. It may appear in the infant's blood in less than twenty-four hours. The weakening of agglutinating power is due to the obstruction to its passage in the mammary gland and in the nursling's digestive tract. The chief factor governing transmission is the intensity of the power in the maternal blood. A subordinate but important factor is some unknown condition in the digestive tract. If the power in the maternal blood is weak and the obstacles great it may not be transmitted.

120.—See abstract in The Journal, xxxv, p. 1049.

121. **Measles.**—Cotter has investigated an epidemic of measles, including 187 cases, to ascertain the following points regarding the presence or absence of Koplik's spots: 1, whether they appear regularly; 2, whether they appear before other pronounced diagnostic signs; 3, to estimate their value in diagnosis. He found positive occurrence of spots in 169 cases, negative in 8 and doubtful in 10. Their absence was observed in poorly nourished children of the marantic or rickety type, or with the taint of hereditary or acquired syphilis. A very small percentage of otherwise healthy children did not show the Koplik spots at any stage of the disease. Two of the 8 were of this character. As regards the time of appearance they occurred with fever and skin eruptions in 78 cases. They appeared one day before the skin eruption in 54, two days before in 25, three days in 4, four days in 3 and five days in one and in 2 cases one day after the eruption. In one case also they appeared with no skin eruption. He is inclined to think from his observations that when measles reaches the stage of appearance of this symptom exposure to other children has been great, but he admits their extreme value as a diagnostic point and knows of no other disease than measles that presents them.

122. **Vapo-Cresolene.**—Adams reports two cases of poisoning from inhalation of the fumes of a vapo-cresolene lamp and reports these because this disinfectant is often used where there is a child that has a cough, and frequently, he thinks, with great risk to it.

131. **Ligature of Innominate.**—Bennett reports an additional case to the twenty-nine already published, of which he gives a summary. His operation was made in the French Congo territory on a native, and the results seemed to be good until the third day, when secondary hemorrhage occurred, carrying the patient off.

132.—See abstract in The Journal xxxv, p. 448.

133. **Creosotal.**—Frankle has found in a few cases of acute lobar pneumonia, creosotal, which is simply a fanciful name for pure and modified forms of creosote carbonate, containing 92 per cent. of creosote, to give apparently valuable results. The cases were all of average severity, with the usual complications, ranging in temperature from 102 to 105. After a preliminary 10-gr. dose of calomel, creosotal was administered in dram doses night and morning and nitroglycerin given as required. The results were diminution of temperature without cardiac depression, a liquefaction of the exudate, general stimulation of all the emunctories and relief from previously existing pain. All the patients got well by gradual defervescence. He thinks the remedy is worthy of a more extended trial.

134. **Yeast Fungus.**—Three cases of apparent diphtheria are reported by Hickey in which the cultures revealed nothing but yeast cells in two; the other, occurring at the same time though less severe, was not examined. The clinical symptoms were very like those of diphtheria, but there was no very extensive glandular enlargement in any of the cases and practically none at all in two.

136.—See abstract in The Journal, xxxv, p. 707.

137.—Ibid.

147.—See abstract in The Journal, xxv, p. 1050.

152. **Caustics in Malignant Disease.**—McGavran believes that caustics have no place in the treatment of cancer of the tonsils, tongue, eyelids, scrotum, penis and rectum, nor would he use them in cancer of the breast or uterine cancer. All objections to caustic treatment disappear when we come to consider cutaneous cancer, and he reports five typical cases of facial eruptions successfully thus treated. The choice of proper escharotics is of great importance. A mild caustic should never be employed. Nitrate of silver and mineral acids should never be employed. Caustic potash, arsenous acid, and chlorid of zinc have given the best results. The one which has given him the best results is Bougard's caustic compound, as follows: Wheat flour, 60 grams; starch, 60 grams; arsenic, 1 gram; cinnabar, 5 grams; sal ammoniac, 5 grams; corrosive sublimate, 0.50 gram, solution of chlorid of zinc at 52 F. .245 grams. The first six substances are separately ground and reduced to a fine powder. They are then mixed in a mortar of glass or china, and the solution of chlorid of zinc is slowly poured in, while the contents are rapidly moved with the pestle, so that no lumps shall be formed. A thick layer is then spread on cotton and left in position from ten to twenty-four hours. If the application has been successful all the macroscopical cancer mass should appear to be necrosed completely and the tissue beyond inflamed. Warm poultices are applied until the slough separates, usually in three days. Few cases require a second application. The ulcer may be dressed with aristol ointment. All exuberant granulations are to be kept in check by the usual methods. It is important to so stimulate the ulcer as not to permit scabs to form. He has used the caustic potash a few times before using Bougard's formula. He has never used Marsden's paste. The patient must be treated energetically and pain not be a preventive. During the application of the caustic he usually gives a hypodermic of morphin every five or six hours, but some cases do not require it.

156.—This article has appeared elsewhere. See The Journal, xxxv, p. 616.

165.—See abstract in The Journal, xxxv, p. 1501.

FOREIGN.

British Medical Journal, December 8 and 15.

Parasitology of Malaria. Lord Lister.—The author reviews the history of the discovery of the origin of malaria from Laveran's first findings of the ameba and Golgi's latter recognition of the tertiary and quartan forms, and the slightly later discovery of the estivo-autumnal parasite. He then gives an account of the deductions of Manson from the findings, and Ross's observations in India, which demonstrated the part that the mosquito plays in the infection. Although this was done, there still remained a link wanting in the chain of biologic sequence. The relation of unpigmented flagella to the pigmented corpuscle was unexplained until MacCallum's observations in this country, when he demonstrated the process of fertilization and that the flagella were nothing more nor less than spermatozoa and the granular cells were ova. The further observations of Koch and Grassi of the life cycle of the parasite, and the observations of Bastianelli and Bignami of the development of crescents, are also noted, as well as the recognition of the anopheles as carrier of the malarial parasite that infects man. Christophers and Stephens have also investigated blackwater fever and the special liability of children to be infected among the natives of malarial regions, with the practical inference from the fact of the advisability of Europeans when settling in a malarial tropical region separating their dwellings from those of natives, the interval of one-quarter of a mile usually being sufficient to afford a suitable degree of protection.

Causes and Cure of Insomnia. JAMES SAWYER.—The hypnotic drugs are reviewed in this second lecture, and Sawyer insists on the importance of giving such only in exceptional cases and of avoiding them if possible. The risks of the administration of a powerful hypnotic are very serious and many human lives are yearly lost from this cause. He would use them only as temporary remedies when it is necessary to secure sleep at once. The patient should never be allowed to swallow chloral or any other dangerous but valuable hypnotic according to his own free will, nor should he proportionate the dose himself. He can only safely take them under medical supervision. Another important point is that an overworked individual must never be permitted to go on with his overwork and habitually secure sleep by chloral or other drugs. The sleeplessness must be attacked at its cause. Sawyer, however, advises suspicion as to accepting work as the cause of insomnia. It is mostly worry, not overwork, or if work, work under wrong conditions. The general hygienic considerations must not be overlooked. A holiday with complete change of scene and with distinct activities will often do much to cure, and if the patient is well nourished the bromids may be cautiously employed. In the anemic cases a generous diet and alcohol as a hypnotic are sometimes useful, but there is a danger in the prescription of this agent and we must not be negligent of our responsibility. The author notices the various plans of producing sleep, such as counting, thinking of monotonous subjects, taking deep inspirations. He thinks these are occasionally useful, but by no means invariably effective. Care should be taken that the bed-covering is sufficient, but not excessive. In all cases, a window should be open the year round. The head of the bed should be away from the wall. A little food taken just at the time of retiring is often effective. Sometimes a person who has been long awake will fall asleep at once after sousing his head, neck and hands in cold water, or shaking up and cooling his pillows and bedclothes and then going back to bed. In the toxic forms of insomnia we must look after a reduction in the consumption of tobacco, alcohol, tea, etc., as the case may be. The treatment of gouty insomnia and that from chronic kidney disease is too extensive a subject, involving as it does the whole question of therapeutics of the maladies on which the symptom depends, to be discussed here. In the very obstinate senile insomnia the bromids with full doses of hops or henbane are the best drugs, and less harmful methods like some of the non-medicinal measures referred to may bring about sleep.

December 15.

Polyorrhomenitis, or Combined Serous Inflammations. FREDERICK TAYLOR.—In this article Taylor describes conditions which have been specially noticed by the Italians and have received the name of polyorrhomenitis, which include multiple serous inflammations. The name can be compared with that of polyarthritis, by which we mean multiple inflammation of the joints, and in these cases also we have to consider what are its bacteria, or poisons that cause the condition. Polyorrhomenitis may be either acute or chronic, and the causes correspondingly different. In the acute case one cause may be pneumococcic, while the pericardium and pleura are inflamed together; another is the staphylococcic invasion, which we see in pyemia and septicemia. The tubercle bacillus is also a cause in a small number of acute cases, though it plays the greatest part in the chronic and subacute inflammation of the serous membranes, where it is the most frequent cause of all. Polyorrhomenitis is more frequent in males than females. The majority of the cases occur between the ages of 16 and 30. In any case it usually begins in one serous membrane and subsequently invades the others, according to the following three types, of which the first is the most frequent and the last mentioned the least: 1. The peritoneum is first attacked, then the pleura, beginning generally with the right pleura. 2. The pleura, then the peritoneum. 3. The pleura on one side is first invaded, and then the opposite. 4. Pericarditis generally follows a pleurisy, and especially a left-sided pleurisy. 5. The inflammation may first involve one pleura, then the peritoneum, then the other pleura. The interval between the invasion of the different sacs may be weeks or months. The duration is also variable, and the result may be recovery with adhesions, or fatal. While most such cases are tuberculous, the author does not exclude the possibility of an exception and mentions a case in which there was no evidence in the post-mortem to show that tubercle had anything to do with the causation. The prognosis depends largely on the cause. The prognosis of pneumococcal polyorrhomenitis is undoubtedly much worse than the prognosis of pneumococcal pneumonia, or a pneumococcal empyema or pleurisy. An implication of the pericardium is a bad addition to the case. Streptococcal and staphylococcal cases may be fatal, but in the subacute or chronic multiple inflammation due to tubercle the prognosis is much more favorable. Tubercular peritonitis is probably fatal in more than one-half the cases; pleurisy in much less, but the associated lesion is not likely to be less fatal than the more fatal of the two operating alone. The course of tuberculous pericarditis probably renders death almost certain. In case of recovery from all the immediate inflammatory conditions there remains the risk from permanent adhesions, the risk of the development of tubercle in other organs, especially the lungs and meninges. The treatment of the condition must be conducted on the lines of treatment of the separate tuberculous lesions concerned, hygienic food, pure air, climate, relief from cares, etc. Internally as drugs, iron, creosote and cod-liver oil have been administered. As to local measures he has aspirated the left chest and applied mercurial ointment externally. Mercurial inunctions have often seemed to be valuable. Laparotomy may become desirable. Arsenic and iodin are also mentioned.

The Lancet, December 8 and 15.

Prognosis and Treatment in Pulmonary Tuberculosis. ROBERT MAGUIRE.—In this second lecture Maguire continues the subject of the prognosis of tuberculosis. Pyrexia, he thinks, is not so significant; it may be absent, and he does not consider that tubercular poisoning itself often produces pyrexia, but rather that it is due to staphylococcal and pneumococcal poisoning. An increased morning temperature and the nearer the approach to evening temperature the worse the outlook for the patient. General weakening at the commencement of the attack greatly increases the gravity of the case. This is especially so if there is a cardiac or vasomotor weakness. Hemoptysis causes altogether too much alarm, especially in the early stages; it occurs from so many other causes that he says: "I think one may say that hemoptysis alone is most frequently not caused by lung disease." Repeated small hemoptyses are often a relief to an over-congested pulmonary area and a single large hemoptysis without fever is apparently of little importance, but if fever is present it should excite all attention. In the second stage, that of progress, a point that we should look out for is the presence of large bubbling râles indicating formation of cavities which may or may not be detected during life, indicating progress of the germ and extension of its action. Pyrexia alone is not a specially important symptom in these cases. Extension of the tubercular lesions of the lungs may take place in five ways, each of which is discussed: 1, by simple contiguity; 2, by lymphatic absorption; 3, by bronchial insufflation, a matter of greatest importance; 4, by venous conduction; 5, by arterial conduction. The lymphatic absorption undoubtedly plays a great part in the extension of contiguity and it may be carried to remote parts of the body in this way. Bronchial insufflation is much more important, and the extension from the apex to the lower lobes is largely in this way. Venous and arterial conductions are, of course, important and more serious than some of the other methods. Tuberculosis of the larynx is never, he holds, an early condition; it is always produced by infection of the larynx through the excretion of the lungs. The same is true of infection of the bowels through swallowing of sputum: both, of course, are of the gravest prognosis. As regards symptoms, there are only two which greatly help in the prognosis in the second stage. They are pyrexia and hemoptysis. The former is always present; the higher the fever and more nearly the morning temperature approaches that of the evening, the worse the prognosis; but still worse is the so-called hectic fever, where the subnormal morning temperature is followed by an evening rise of perhaps even 8 degrees. Maguire's experience shows that no drug has any effect on this symptom. Hemoptysis is much more serious in the second stage than in the first, inasmuch as it is more usually caused by ulceration of the blood-vessels. Its dangers are: 1, loss of blood; 2, shock; 3, fright. He has seen cases where this last caused the death. In the third stage we have signs of activity and consolidation, or loss of lung tissue, dyspnea and hemoptysis, which last is a very serious matter. If copious it is most frequently caused by rupture of an aneurysm of the pulmonary artery in a cavity, and he warns against reckless percussion in this stage on account of the possible presence of these aneurysms.

December 15.

Prognosis and Treatment of Pulmonary Tuberculosis. Robert Maguire.—The third lecture deals with treatment. First he notices the encouraging resistance of the tissues by feeding, and the open-air treatment, which he thinks is carried to excess at the present time and should be tempered by good judgment on the part of the physician; then he passes to his experiments on producing asepsis of the lungs or destruction of the tubercular germs by injections of glycogen, yeast, cyanid of mercury, taka-diastate and nuclein with some little apparent encouragement with some of these, but the difficulties were very pronounced. He then gives a report of his own experiments with intravenous injection of a weak solution of formaldehyde, which is noticed editorially in this issue of The Journal. An unpleasant experiment on himself showed that it is dangerous to use a solution of more than 1 in 2000, and the maximum injection should not exceed more than 50 c.c. for an adult. The result of his treatment as elsewhere noticed has been encouraging, but he suggests that if unduly continued the formaldehyde will irritate the lung tissue and increase the symptoms. It is only practice and experience than can show one when to stop the treatment, but as a general rule he thinks it advisable to give up the injections for a few days when the temperature has fallen, when the sputum has become mucous and frothy, and when the cough is unduly troublesome. With regard to the latter he does not see the objection to the judicious use of opium to relieve both the excessive secretion and cough.

Bulletin de l'Academie de Med. (Paris), December.

Treatment of Fracture of Humerus. Lucas-Championniere.—As further evidence of the superiority of his method of early massage, without immobilization, Lucas-Championniere exhibited a man of 63 who had been treated for a fracture of the humerus below the deltoid impression, which had occurred a month previously. In spite of a certain degree of deformity there is no pain and the patient can already commence to use his arm. The treatment should be begun from the very first; it is impossible to attain the same results if the massage is not commenced until a few days after the traumatism. The pain and the contractions of the early stage should be prevented.

Neuropathic Hemorrhages of the Digestive Passages. Lancereaux.—The mouth, stomach or intestines may be the seat of neuropathic hemorrhage. It may appear consecutive to an emotion and is rarely serious unless by its repetition. There are almost always premonitory symptoms, a sensation of pain and oppression in the epigastrium, and of pain in the lumbo-sacral region or at the anus, genital regions or in the cecum, with general oppression, anorexia, flatulency and pains in the legs. These symptoms are followed by more or less pronounced colic and fluid, blackish stools, with a depression which may terminate in melancholia or syncope. The pulse and respiration become more rapid. These symptoms sometimes increase to such an extent as to become actually threatening, but usually the hemorrhage moderates and the patient recovers his strength. Recurrences are frequent and are sometimes periodical for several years. Opiates are useful by immobilizing the alimentary canal, combined if necessary with ice on the abdomen, injections of ergotin, and if the hemorrhage is from the stomach by the injection of twenty drops of ferric chlorid in solution. Quinin is extremely effective in arresting neuropathic hemorrhage, in doses of from 1 to 1.5 gm. a day. A number of typical cases of neuropathic hemorrhage are described, emphasizing the absence of anatomic lesions in these cases and the neuropathic character, especially in persons with a tendency to gout or rheumatism.

Bulletin Medical (Paris), December 1.

Vasoconstricting Properties of Quinin. Huchard.—The lowered arterial pressure that characterizes la grippe explains the beneficial results of the administration of quinin, owing to its power of contracting the vessels. This property renders it useful in various congestive and hemorrhagic conditions, combined with ergot and digitalis in case of hemoptysis or with opium and antipyrin in metrorrhagia with lumbo-abdominal pain which does not yield to ergot. Paulesco has reported two cases of exophthalmic goiter very favorably influenced by 1 gm. of quinin a day, and Soulier has had a similar experience with two cases treated with .75 gm. a day for a month. Huchard has been treating six cases of this disease with quinin hydrobromate for several months, 1.5 gm. a day during the first week, 1 gm. during the second, and .5 gm. during the third, and then recommencing with 1.50 gm. The results attained in four of the six cases have been extremely encouraging. Quinin is also very useful in aortic insufficiency with violent pulse-beat in the arteries of the neck and with nervous symptoms. He has also derived great benefit from it in thirty cases of what he calls "orthostatic" tachycardia, the disturbances in the circulation appearing only when the subject stands, diminish as he sits, and vanish completely when he reclines. The vascular system is relaxed and the heart contracts the more rapidly the more easily it is emptied. Ergot is ineffective in these cases.

Bull. de la Soc. Med. des Hop. de Paris, November 29.

Puerperal Phlebitis. Stapfer.—A slight, persisting subfebrile condition after childbirth is a warning of approaching phlebitis. In a case described, it continued for six to seven days when the temperature rose apparently to normal for ten days. Fever then returned and phlebitis of one of the lower limbs became evident, involving later the other limbs. After fifteen days of fever and phlebitic symptoms the fever rose to 41 C. and accompanied by intense headache and nervous symptoms. A course of frequent and prolonged tepid baths gradually restored conditions to normal, the patient becoming convalescent on the fifteenth day. These prephlebitic and postphlebitic symptoms are evidently due, like the phlebitis itself, to migration of microbes or toxins.

Revue Hebd. de Laryngologie (Bordeaux). November 10 and 24.

Primary Tuberculosis of the Larynx. S. Bernheim.—The larynx is more frequently the seat of primary localization of tuberculous infection than is generally appreciated. Bernheim has observed twenty-nine cases of this condition, and remarks that it can be differentiated by the small miliary vesicles which break and unite to form shallow, irregular flat ulcerations which invade almost the entire organ. The slow progress and the general phenomena distinguish it from primarily inflammatory laryngitis. He has sometimes injected tuberculin to aid in the diagnosis. It produces a harmless local pathognomonic reaction. The proper treatment aims to make the organism strong enough to live with the bacilli without suffering from their inroads. Fresh air, rest and food produce unexpected results and should be the base of all treatment of primary laryngeal tuberculosis. In the first stage phenic and lactic acid are the best local remedies, and in the other stages sprays or inhalation of phenic acid, repeated at least four times during the day. Senesse prescribes the following solution for the purpose: Phenic acid, 30 to 60 cgm.; cherry-laurel water, 20 gm.; potassium bromid or borax, 2 to 3 gm.; neutral glycerin 30 gm.; aq. dest. 300 gm.

November 24.

Operative Treatment of Scleroma. E. de Navratil.—Scleroma is more frequent in the eastern portion of central

Europe than in the west, especially in Hungary, Roumania, etc. Navratil does not allow himself to be deterred from operating by the advanced condition of the lesion, and reports several cases completely cured without recurrence by excising all the invaded regions and far into sound tissue, with subsequent autoplasty. He also describes a case which—unoperated—progressed to fatal involvement of the upper air-passages.

Ether in Laryngeal Tuberculosis. L. VACHER.—Intratracheal injections have been found by the writer very effective in treating tuberculosis of the larynx, especially in the ulcerative stage, in which there is usually much pain, a rebellious cough and laryngeal spasm. To control these symptoms and treat the lesion, he has found the following formula most satisfactory, after innumerable trials of various substances for these intratracheal injections. Ether with iodoform to saturation, 100 c.c.; guaiacol, 5; eucalyptol, 2; and menthol, 1, injecting 2 c.c. at a time. The patients all prefer the solutions made with ether as much more agreeable than when any other vehicle is employed. There is no spasm of the glottis, probably because the gas generated in the trachea forces it open. The improvement is unmistakable, both local and general, after a course of these intratracheal injections.

Semaine Medicale (Paris), December 5.

Plastic Linitis. BRISSAUD.—In the fibrous or fibroid tissue which forms the compact mass of the hypertrophied pylorus in this affection, there are always strips of epithelioid cells whose nature is still disputed. Some insist that they are metatypical elements, others that they are cancerous or that they are merely lymphatic endothelium and that the process is therefore an inflammatory tumefaction. The affection is first manifested by dyspepsia, with characteristics resembling those attributed to chronic gastritis. The morning mucus is exceptional, however, and when vomiting occurs, the food is seen to be largely digested. The vomiting is not always of food, as long as the syndrome of stenosis of the pylorus is not complete. The general health becomes rapidly modified from the very first, in spite of the good appetite and persistence of gastric digestion. The extreme pallor without hematemesis or melena suggests the anemic form of cancer. The legs are edematous, but the debility is not proportional to the cachectic appearance. A tumor soon appears at the pylorus; this is not knobby nor definitely limited, but it feels like a simple thickening of the stomach wall. The stomach is not dilated and sometimes is even retracted, especially in total linitis accompanied by retroperitonitis. The tumor always retains its primary site. A case is described in detail, treated by pylorectomy which restored the patient as if by magic. In nineteen days he had gained 1.2 kg. In another week, 2.1 kg. additional and by the end of four or five months he had gained a total of 10.62 kg.

Berliner Klin. Wochenschrift, November 26.

Treatment of Septic Infection Proceeding from the Uterus. ABEL.—Bacteriologic examination is of great importance and should be the guide in treatment. Irrigation of the uterus is of very little value, as the fluids do not penetrate into the tissue. Atmokausis is preferable—cauterization with steam. Abel relates instances in which the temperature fell to normal after exposure of the inner surface of the uterus to the action of steam at 110 C. for thirty seconds. The eschar formed was expelled later almost entire. He advocates atmokausis always as a last resort before proceeding to extirpation, reserving the latter for cases of infection in which there are extensive lacerations of the uterus. Extirpation transforms the dangerous lesion into a smooth wound with a prospect of healing. Infusion of salt solution and inhalation of oxygen are valuable adjuvants.

Centralblatt f. Chirurgie (Leipsic), December 8.

Improved Drill. P. MEISEL.—The grooves in the ordinary drill soon fill up with bone dust. Meisel overcomes this difficulty by making his drill as if it were two cutting knives rotating above a dura protector. By holding the drill obliquely a flat bone can be cut through at any angle or in an arc. Kraske has been using this drill in resecting the jaw and trephining for two years. A trephine flap cut with sloping edges fits back in place so perfectly that the patient can lie on it without trouble even from the first.

Cbl. f. Gyn. (Leipsic), October 27 and November 24.

Complete Rupture of the Uterus. K. J. F. BAUR.—In a case reported by Baur the spontaneous rupture was complete; fever and hemorrhage were slight, but there was considerable collapse. The dead fetus was extracted with forceps and the placenta found among the intestinal loops by following the cord with the hand. The ruptured uterus and the vagina were merely tamponed and the patient recovered without further treatment. When dismissed a month later, the uterus was in normal involution. It was retroflexed but readily straightened. No adhesions could be felt. A cicatrix extended along the posterior right vaginal wall. There was a gap in the cervix the width of the finger and it continued up in the broad ligament for 7 cm. Abstention from surgical intervention, even from local irrigation, permitted all the physical forces to be concentrated on the repair of the lesion and to this Baur attributes the favorable results of conservative treatment in such cases.

November 24.

Chorio-epithelial Vaginal Tumors. H. SCHMITT.—In the last three years cases have been reported of multiple, true chorio-epitheliomata in the vagina, lungs, liver and intestines with no primary tumor in the uterus. Schlagenhaufer has recently observed a case in which a chorio-epithelioma of the vagina was removed nine months after an abortion, with complete recovery. Schmitt reports a similar case operated on at Schauta's clinic. Two malignant chorio-epitheliomata had developed in the vagina, first noticed three months after the spontaneous expulsion of a hydatid mole with only a few days of fever but considerable hemorrhage, almost continuous for six weeks and recurring twice afterward for a few hours. One tumor was the size of an egg and the other of a nut when removed two months later. The general health was good and the uterus appeared normal. As curettement disclosed only ordinary interstitial endometritis, the uterus was left undisturbed. The patient has been examined every few weeks during the past eight months and seems normal in every respect. The malignant neoplasms in the vagina probably developed secondarily from normal villi deposited at this point during delivery. It is possible that this villous tissue may be carried to other organs by the blood, but perishes there from lack of a suitable soil.

Cbl. f. Inn. Med. (Leipsic), November 17, 24, and December 1.

Bacteriology of the Blood in Pneumonia. A. PROCHASKA.—Pure cultures of the pneumococcus were derived from the blood of each of ten cases of pneumonia tested at Eichhorst's clinic. Four terminated fatally; the remainder recovered, with empyema in one case and unusually slow absorption in some of the others. Nephritis and gangrene of the lungs occurred in three of the fatal cases.

November 24.

Action of Distillate of Coffee and Tea on Respiration and Heart. C. BINZ.—From eighteen tests on man and three on dogs, Binz concludes that the distillate of roasted coffee—free from caffein—has a marked effect, temporarily increasing the number of respirations. Muscular agitation and slight psychic excitement were also noted. The distillate of tea produced similar, but less pronounced, effects.

December 1.

Treatment of Senile Pruritus. A. JAENICKE.—Systematic brushing with a soft brush will remove the dead epithelium cells from the surface of the skin, which Jaenicke thinks is frequently the cause of senile pruritus. The skin can be moistened with alcohol to enhance the effect during the first two days, or lard or lanolin can be used for the purpose. Vaselin is less effective. Warm baths soften the epidermis and annul the effects of the brushing, which should be done for ten to twenty minutes at a time, three times a day at first, gradually diminishing to once in two days. This treatment has the second stage. They are pyrexia and hemoptysis. The former is always present; the higher the fever and more nearly the morning temperature approaches that of the evening, the worse the prognosis; but still worse is the so-called hectic fever, where the subnormal morning temperature is followed by an evening rise of perhaps even 8 degrees. Maguire's experience shows that no drug has any effect on this symptom. Hemoptysis is much more serious in the second stage than in the first, inasmuch as it is more usually caused by ulceration of the blood-vessels. Its dangers are: 1, loss of blood; 2, shock; 3, fright. He has seen cases where this last caused the death. In the third stage we have signs of activity and consolidation, or loss of lung tissue, dyspnea and hemoptysis, which last is a very serious matter. If copious it is most frequently caused by rupture of an aneurysm of the pulmonary artery in a cavity, and he warns against reckless percussion in this stage on account of the possible presence of these aneurysms.

December 15.

Prognosis and Treatment of Pulmonary Tuberculosis. ROBERT MAGUIRE.—The third lecture deals with treatment. First he notices the encouraging resistance of the tissues by feeding, and the open-air treatment, which he thinks is carried to excess at the present time and should be tempered by good judgment on the part of the physician; then he passes to his experiments on producing asepsis of the lungs or destruction of the tubercular germs by injections of glycogen, yeast, cyanid of mercury, taka-diastate and nuclein with some little apparent encouragement with some of these, but the difficulties were very pronounced. He then gives a report of his own experiments with intravenous injection of a weak solution of formaldehyde, which is noticed editorially in this issue of THE JOURNAL. An unpleasant experiment on himself showed that it is dangerous to use a solution of more than 1 in 2000, and the maximum injection should not exceed more than 50 c.c. for an adult. The result of his treatment as elsewhere noticed has been encouraging, but he suggests that if unduly continued the formaldehyde will irritate the lung tissue and increase the symptoms. It is only practice and experience than can show one when to stop the treatment, but as a general rule he thinks it advisable to give up the injections for a few days when the temperature has fallen, when the sputum has become mucous and frothy, and when the cough is unduly troublesome. With regard to the latter he does not see the objection to the judicious use of opium to relieve both the excessive secretion and cough.

Bulletin de l'Academie de Med. (Paris), December.

Treatment of Fracture of Humerus. LUCAS-CHAMPIONNIERE.—As further evidence of the superiority of his method of early massage, without immobilization, Lucas-Championniere exhibited a man of 63 who had been treated for a fracture of the humerus below the deltoid impression, which had occurred a month previously. In spite of a certain degree of deformity there is no pain and the patient can already commence to use his arm. The treatment should be begun from the very first; it is impossible to attain the same results if the massage is not commenced until a few days after the traumatism. The pain and the contractions of the early stage should be prevented.

Neuropathic Hemorrhages of the Digestive Passages. LANCEREAUX.—The mouth, stomach or intestines may be the seat of neuropathic hemorrhage. It may appear consecutive to an emotion and is rarely serious unless by its repetition. There are almost always premonitory symptoms, a sensation of pain and oppression in the epigastrium, and of pain in the lumbo-sacral region or at the anus, genital regions or in the cecum, with general oppression, anorexia, flatulency and pains in the legs. These symptoms are followed by more or less pronounced colic and fluid, blackish stools, with a depression which may terminate in melancholia or syncope. The pulse and respiration become more rapid. These symptoms sometimes increase to such an extent as to become actually threatening, but usually the hemorrhage moderates and the patient recovers his strength. Recurrences are frequent and are sometimes periodical for several years. Opiates are useful by immobilizing the alimentary canal, combined if necessary with ice on the abdomen, injections of ergotin, and if the hemorrhage is from the stomach by the injection of twenty drops of ferric chlorid in solution. Quinin is extremely effective in arresting neuropathic hemorrhage, in doses of from 1 to 1.5 gm. a day. A number of typical cases of neuropathic hemorrhage are described, emphasizing the absence of anatomic lesions in these cases and the neuropathic character, especially in persons with a tendency to gout or rheumatism.

Treatment of Senile Pruritus. A. Jaenicke.—Systematic brushing with a soft brush will remove the dead epithelium cells from the surface of the skin, which Jaenicke thinks is frequently the cause of senile pruritus. The skin can be moistened with alcohol to enhance the effect during the first two days, or lard or lanolin can be used for the purpose. Vaselin is less effective. Warm baths soften the epidermis and annul the effects of the brushing, which should be done for ten to twenty minutes at a time, three times a day at first, gradually diminishing to once in two days. This treatment has always relieved the pruritus and frequently abolished it for several months at a time.

Cbl. f. Nerv. u. Psych. (Breslau), October.

Hypothermia in Epilepsy. C. Ceni.—In twelve out of twenty epileptics Ceni has examined, the temperature fell to 36, 35, and even 34 C. at times, the hypothermia persisting for thirty to sixty minutes. In some cases it recurred several times during the twenty-four hours, but usually appeared after periodical intervals of a few days or weeks, but at irregular hours. In some patients, however, it reappeared with an intermittent character at about the same hour. There did not seem to be any connection between the hypothermia and the number or violence of the seizures, but in a few cases it preceded a seizure by an hour or two. He considers this hypothermia another point in favor of the autotoxic nature of epilepsy.

Deutsche Med. Wochenschrift (Leipsic), December 6.

Typhoid Bacilli in the Blood. M. Auerbach.—By the technique described, Eberth's bacillus was discovered in the blood in seven out of ten cases of typhoid fever of varying severity. Differentiation was possible in some instances in thirty-six hours. About 300 c.c. of meat bouillon in an Erlenmeyer jar were sown with 10, 20 or 30 drops of blood from the median vein and shaken. Hanging-drop cultures made in eighteen to twenty-four hours afterward were sometimes successful, but in other cases the jars required replacing in the oven for twenty-four more hours. By this means characteristic cultures could be obtained on agar, milk, grape sugar and bouillon and the eight-hour bouillon culture proved a fine test for the agglutinating properties. In one case an uncertain diagnosis was confirmed by the results of this test of the blood. It is as simple a procedure as the agglutinating test and is decisive if positive.

Neurologisches Centralblatt (Leipsic), November 1 and 15.

Electric Stimulation After Decapitation. A. Hoche.—Hoche's electric tests of decapitated criminals have already been mentioned in The Journal. He has since had opportunity for research on two more subjects, commencing two minutes after the knife had fallen, and it confirms his previous views. He finds that there is no independent excitability to the faradic current on the part of the motor fibers in the tracts. The effects which follow electric stimulus are due either to stimulation of the roots or to reflex mediation. By graduating the amount of the stimulus, these latter forms can be differentiated. Weak stimulation of the anterior and lateral columns of the cord induces contraction on the same side, and stronger stimulus, symmetrical contraction on the other side. Weak stimulation of the posterior columns produces a symmetrical response in the plane of the point of excitation. The question of the localization of the ganglion cells for the nerves of the upper extremity can probably be determined by isolated stimulation of the anterior roots, which he proposes to undertake on the next occasion.

November 15.

Brachial Neurosis from Diseased Tooth. F. Hesse.—A tooth which had been filled six years before was not particularly painful and appeared sound, but both jaws were tender and violent pains radiated through the shoulder, breast and arm, with paralytic symptoms. Extraction of the tooth, which proved to have a necrosed pulp, completely cured the neurosis in the cervical and brachial plexuses which had resisted all treatment for a year.

Wiener Klinische Rundschau, November 25.

Cerebral Bladder Disturbances. E. von Czyhlarz and O. Marburg.—In this communication, based on observations at Nothnagel's medical and Obersteiner's neurologic clinics, the writers announce that bladder disturbances may exist in the course of cerebral affections with an otherwise sound nervous, muscular and glandular bladder apparatus, and without clouding of the consciousness. Unilateral lesions of the motor zone of the cortex caused disturbance of the bladder function, as was shown in an inability to voluntarily void urine. No bilateral lesions came under observation. The surprising fact was also noted that the subcortical cerebral centers seem to have a certain influence on the bladder. In several cases of lesions of the corpus striatum, there was incontinence of urine, but in a case of bilateral, total destruction of the thalamus, there were no bladder disturbances, although the knee reflexes were abolished.

Connection Between Lithiasis and Hard Water. J. Preindlsberger.—The writer has been making an extensive study of lithiasis in Bosnia and gives a map showing that all of the 176 cases of lithiasis he has been able to collect, occurred in a central district stretching through the country, corresponding to a certain geological foundation, consisting essentially of lime.

Wiener Klinische Wochenschrift, November 29.

Plea for More Extensive Operating in Carcinoma Uteri. E. Wertheim.—During the last two years Wertheim has been having many sections made of the glands and parametrium in every case of cancer of the uterus that came to operation, 33 in all. In 11, some of the glands in the region were found invaded by the carcinoma, including five in which the neoplasm had been supposed to be in its earliest stage. That is, in 26 cases of operable carcinoma of the cervix the glands were found involved in 20 per cent. In one case, a commencing cancroid of the portio, a cancerous gland about the size of a cherry, was found close to the right external iliac vein. No traces of cancer could be discovered in any of the other glands nor in the parametrium. In another case, a circumscribed nodule on the posterior lip of the portio vaginalis was accompanied by a cancerous gland, the size of a hen's egg, on the left external iliac vein. In the third case the cervix was entirely cancerous and a cancerous gland was found close to the right uterine vein. In the fourth, the cervix was cancerous, and the parametrium and neighboring glands were normal, but at the point where the left ureter crosses the common iliac, a cancerous gland the size of a cherry was found. In the fifth, a narrow strip of cancerous tissue in the right parametrium led to a very large cancerous gland adherent to the external iliac vein. Cancerous fibers and nests were found several times in the parametrium, when to the eye and touch it seemed perfectly normal. Wertheim considers these findings important testimony to the necessity of extirpating the glands in the vicinity and the parametrium in all cases. His technique includes exposing and liberating the ureters and the iliac blood-vessels. The glands are carefully sought for along the vessels and excised, up to the fork of the abdominal aorta, and the parametrium and paravaginal cellular tissue are extirpated with the uterus and the upper portion of the vagina. Omitting light inoperable cases, he has had three die out of 25 patients operated on, one from invagination of the small intestine, the others from peritonitis. The remainder recovered and have shown no signs of recurrence to date. The operation requires seventy-five to ninety minutes. The ureters are easily isolated unless fixed by inflammatory processes. The vessels are readily exposed. Hemostasis has to be applied to even the smallest ramification of the veins and trained assistance is necessary. Provisory ligature of the hypogastric artery was of no appreciable benefit. The extirpation of the glands is difficult only when they are adherent to the vessels. In future, he remarks, it may be possible to restrict the extirpation to those glands alone which are tumefied, as in none of his sections were traces of carcinoma to be found in the normally small glands. The general health and the state of the heart should be carefully weighed before attempting intervention. If these are favorable, unexpectedly gratifying results may be attained.

Differential Diagnosis Between Tubercular and Syphilitic Processes. P. Baumgarten.—In a syphilitic process the small fibroblasts only exceptionally attain the size and the number of nuclei of the tubercular epithelioid cells. They are also regularly distributed and covered with leucocyte infiltration and the capillaries are prominent. In a tubercular process, the cells are clumped and without leucocyte infiltration, and the presence of even a single giant cell tips the scale of probability. The vessels also soon disappear. Cicatrization occurs only after a caseous degeneration. In a syphilitic process the connective-tissue metamorphosis frequently appears before the gummatous necrosis, which proceeds much more slowly to complete destruction of the parts. The contour of the original structure may be perceived through the veil of gummatous mortification, while in tubercular processes the original structure soon vanishes completely. In the testicles the syphilitic process begins in the interstitial tissue and only secondarily invades the walls of the seminiferous tubules, while the reverse course is observed in a tubercular process. It usually occurs first in the epididymis and spreads through the rete testis to the seminiferous tubules. In only two cases on record were the latter the primary site of tubercular affection. Virchow has also observed a primary interstitial tubercular process in the testis, most common in young boys with general miliary tuberculosis. Another point in differentiation is that a syphilitic process induces degenerative changes in the epithelium of the tubules, while in a tubercular there is always pathologic proliferation.

The Ganglia of the Abdominal Wall in Peritonitis. M. Askanazy.—The ganglia are not as usual woven closely into the tissues, but are surrounded by a space which is seen to be the dilated sheath, filled with a lymphatic fluid. The ganglia are compressed and displaced by the pressure of this fluid and this is probably a factor in the intestinal paralysis which frequently accompanies peritonitis.

Change of Address.

E. Brown, 15th and Dodge Sts., to 1026 Park Ave., Omaha, Neb.

Queries and Minor Notes.

MUSCLE-TRAINING OF INFANTS.

Cortland, N. Y., Dec. 17, 1900.

To the Editor:—Will you please give me the title of a good manual on the muscle-training of infants? What I need is for a child 3 years old that does not co-ordinate properly. F. W. H.

Ans.—We do not know of any special work on the muscle-training of infants or very young children, nor of any one dealing specially with that subject. We believe that the natural play of children is usually the best muscle-training exercise, though in special cases the treatment for imperfect co-ordination would have to be managed on different principles, recognition being taken, of course, of the underlying condition, which may be one that will effect the prognosis.

MEDICAL-PRACTICE LAW.

Wausaukee, Wis., Dec. 24, 1900.

To the Editor:—Would you kindly publish, or tell me where I may find, the requirements for registration for practice in the state of Michigan, and also name and address of the secretary of the State Board of Examiners? Respectfully, R. C. A.

Ans.—The requirements in Michigan are a diploma from a recognized medical college, or examination. The board of examination is rigid in its scrutiny of medical colleges. A list of colleges recognized by the board can probably be obtained from the secretary, Dr. B. D. Harison, Sault Ste. Marie, Mich.

A HOME FOR PHYSICIANS.

Bristol, Tenn., Dec. 11, 1900.

To the Editor:—I write for information as to a matter to which my attention has been called recently and that is to a proposition to build a physicians' home in some part of the United States in the near future. Please let me know if there is such a movement on foot and by whom the movement is projected. I have been asked to find something about the matter, and hence I make inquiry of you. G. M. P.

Ans.—We do not know of any such project being under consideration. Possibly some of our readers may be able to enlighten us.

CALL OF COURTESY.

Roanoke, Va., Dec. 21, 1900.

To the Editor:—I desire to ascertain whether it is customary for a medical practitioner who has just recently located in a city to call on his brother medical men first as an act of courtesy, or should he wait until the first call is made by them? I do not think our Code of Ethics makes any mention of this; at least the one I have (written by Prof. Austin Flint in 1893) is silent on the subject. "The Physician Himself," by Cattell, makes some mention of the subject, but it is not quite clear. Your immediate reply will serve toward settling a lively dispute on the subject.

Fraternally yours, B. C. K.

Ans.—While there is no written law governing the subject, there is an unwritten one that a medical practitioner locating in a city shall call on the other physicians and announce that he is locating among them, and in that way intimate that he desires their recognition.

INTRA-ABDOMINAL TORSION OF THE OMENTUM.

Niagara Falls, N. Y., Dec. 19, 1900.

To the Editor:—Referring to your editorial in The Journal of *Dec. 15, 1900*, page 1558, concerning intra-abdominal torsion of the omentum, I would ask if you could kindly give me some literature on this condition. I have now under my care a case in which I diagnosed some time ago chronic torsion of the omentum, and I hope to be able soon to confirm my diagnosis by an operation. As I intend to publish the case, owing to its interest to the profession, your kind help in collecting the literature would be greatly appreciated. C. G. Leo-Wolf, M. D.

Ans.—The following references are given by Dr. Wiener in his article in the *Annals for Surgery* for November, 1900:

Max Oberst: Zur Casuistik d. Bruchschnittes nebst Bemerkungen über Netzeinklemmungen. Centralbl. f. Chirurgie, 1882.

Maydl: Ueber Retrograde Incarceration d. Tuba u. d. Processus Vermiformis, etc. Wiener Klin. Rundschau, 1894.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Dec. 13 to 19, 1900, inclusive:

Charles H. Andrews, acting asst.-surgeon, leave of absence from the Department of California extended.

John E. Bacon, acting asst.-surgeon, relieved from duty at Fort Du Chesne, Utah, to proceed to Fort Grant, Ariz., and report by telegraph to the surgeon-general for annulment of contract.

Lawrence C. Carr, major and surgeon, Vols., leave of absence granted.

Harold W. Cowper, acting asst.-surgeon, from Fort Ontario, N. Y., to San Francisco, Cal., for duty with troops en route to Manila, P. I., and subsequent assignment in the Division of the Philippines.

William D. Crosby, captain and asst.-surgeon, U. S. A., to report to the president of the examining board, Army Medical Museum, Washington, D. C., for examination for promotion.

Richard M. Fletcher, Jr., acting asst.-surgeon, leave of absence from the Department of Dakota extended.

Timothy F. Goulding, acting asst.-surgeon, on the expiry of his present leave of absence, to proceed from Boston, Mass., to San Francisco, Cal., for duty with troops going to Manila, P. I., and for subsequent assignment in the Division of the Philippines.

George B. Lawrason, lieutenant and asst.-surgeon, Vols. (recently appointed with rank from Nov. 19, 1900), is assigned to the 11th U. S. Cav., Vols.

James H. McCall, acting asst.-surgeon, from Fort Schuyler, N. Y., to San Francisco, Cal., for duty with troops going to Manila, P. I., and for subsequent assignment in the Division of the Philippines.

Adrian S. Polhemus, captain and asst.-surgeon, U. S. A., to report to the president of the examining board, Army Medical Museum building, Washington, D. C., for examination for promotion.

Earle H. Sargent, acting asst.-surgeon, from Fort Casey, Wash., to duty at Camp William H. Osborne, Idaho.

Jesse P. Truax, acting asst.-surgeon, from Camp William H. Osborne, Idaho, to post duty at Fort Casey, Wash.

Compton Wilson, acting asst.-surgeon, from London, Ont., Canada, to San Francisco, Cal., for duty with troops en route to Manila, P. I., and for subsequent assignment in the Division of the Philippines.

Navy Changes.

Changes in the Medical Corps of the Navy for week ending Dec. 22, 1900:

Asst.-Surgeon R. E. Ledbetter, detached from the *Constellation* and assigned to the *Monongahela*.

Asst.-Surgeon J. A. Murphy, detached from the *Solace* and assigned to the *Don Juan de Austria*.

Asst.-Surgeon Jacob Stepp, detached from the *Solace* and assigned to the Cavite naval station.

Asst.-Surgeon M. V. Stone, detached from the *Yosemite* and assigned to the *Isla de Luzon*.

Asst.-Surgeon J. C. Thompson, detached from the Navy Hospital, Cavite, P. I., and assigned to the *Solace*.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ended Dec. 20, 1900:

Surgeon George Purviance, to report at Washington, D. C., for temporary duty.

Surgeon H. W. Sawtelle, granted leave of absence for thirty days from Jan. 20, 1901.

Surgeon J. H. White, bureau letter of Oct. 11, 1900, granting Surgeon White leave of absence for thirty days amended so that said leave shall be for twelve days only.

Surgeon P. M. Carrington, granted leave of absence for thirty days on account of sickness. Relieved from duty at Washington, D. C., and directed to proceed to Fort Stanton, N. M., and assume command of the service, relieving P. A. Surgeon J. O. Cobb.

P. A. Surgeon J. O. Cobb, relieved from command of service at Fort Stanton, N. M., and directed to report to medical officer in command for duty.

P. A. Surgeon M. J. Rosenau, upon completion of duty at Paris, France, to rejoin station as director of Hygienic Laboratory, Washington, D. C.

Asst.-Surgeon John McMullen, relieved from duty at Tortugas quarantine, and directed to proceed to Savannah, Ga., quarantine station for temporary duty.

Asst.-Surgeon W. A. Korn, granted leave of absence for seven days from Dec. 24.

Junior Hospital Steward E. T. Olsen, granted leave of absence for ten days from Dec. 22.

APPOINTMENT.

A. C. Fraser, of Wisconsin, appointed acting asst.-surgeon for duty at the port of Manitowoc, Wis.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Dec. 21, 1900:

SMALLPOX—UNITED STATES.

District of Columbia: Dec. 15, 5 cases.

Illinois: Chicago: Dec. 8-15, 2 cases.

Kansas: Wichita, Dec. 8-15, 11 cases.

Kentucky: Lexington, Dec. 8-15, 2 cases.

Michigan: Detroit, Dec. 8-15, 2 cases.

Minnesota: Minneapolis, Dec. 8-15, 7 cases.

Nebraska: Omaha, Dec. 1-8, 3 cases.

New Hampshire: Manchester, Dec. 8-15, 22 cases.

New Jersey: Jersey City, Dec. 8-16, 1 case.

New York: New York, Dec. 15, 15 cases.

Ohio: Ashtabula, Dec. 8-15, 2 cases; Cleveland, Dec. 8-15, 37 cases: Portsmouth, Dec. 8-15, 2 cases.

Pennsylvania: Erie, Dec. 15, 5 cases.

South Carolina: Greenville, Dec. 8-15, 2 cases.

Tennessee: Memphis, Dec. 8-15, 1 case.

Texas: Houston, Dec. 15, 18 cases.

Utah: Salt Lake City, Dec. 8-15, 40 cases, 1 death.

West Virginia: Wheeling, Dec. 15, 8 cases.

Wisconsin: Milwaukee, Dec. 8-15, 1 case.

SMALLPOX—FOREIGN.

Bohemia: Prague, Nov. 24-Dec. 1, 46 cases, 1 death.

Brazil: Pernambuco, Nov. 15, 16 deaths; Rio de Janeiro, Oct. 16-31, 43 deaths.

Egypt: Alexandria, Nov. 27, 3 cases, 1 death.

England: London, Nov. 24-Dec. 1, 14 cases, 1 death; Sunderland, Dec. 1, 1 case.

France: Paris, Dec. 1, 17 deaths.

Gibraltar: Nov. 25, 1 case.

Greece: Athens, Dec. 1, 2 cases.

India: Calcutta, Nov. 3-15, 8 deaths.

Mexico: Mexico, Dec. 2, 1 case; Tuxpan, Dec. 3-10, 3 deaths

Russia: Moscow, Nov. 17-24, 3 cases, 1 death; Odessa, Nov. 24, 62 cases, 15 deaths; St. Petersburg, Nov. 24, 5 cases, 2 deaths; Warsaw, Nov. 24, 25 deaths.

Scotland: Glasgow, Dec. 7, 45 cases, 1 death.

Spain: Corunna, Nov. 3, 2 deaths; Valencia, Dec. 2, 1 case.

YELLOW FEVER.

Brazil: Rio de Janeiro, Oct. 16-31, 2 deaths.

Mexico: Vera Cruz, Dec. 8, 2 deaths; Yucatan, Nov. 30, 1 death.

CHOLERA.

India: Bombay, Nov. 13-20, 7 deaths; Calcutta, Nov. 3-15, 35 deaths; Madras, Nov. 10-16, 2 cases, 1 death.

Straits Settlements: Singapore, Nov. 3, 6 deaths.

PLAGUE—FOREIGN AND INSULAR.

Brazil: Rio de Janeiro, Oct. 16-31, 9 deaths.

India: Bombay, Nov. 13-20, 125 deaths; Madras, Nov. 10-16, 1 death.

Philippine Islands: Manila, Nov. 3, 3 cases, 1 death.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage, $2.50. Subscriptions may commence at any time. Volumes begin with the first issue of January and of July.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

The qualifications for membership require that the applicant be a member, in good standing, of a state or local medical society entitled to send delegates to the annual meeting of the American Medical Association. A list of these societies will be sent on request. Applications must be accompanied with a certificate showing that the applicant is a member of a recognized society, and should be sent with the annual dues—five dollars—to the treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago. Members receive The Journal free. Subscribers to The Journal may become members of the Association without additional expense if they are members of medical societies recognized by the Association. Those desiring to have their names transferred from the subscription to the membership lists should send certificates as above, with a receipt for their subscription to The Journal, covering the current fiscal year.

FISCAL YEAR.

The fiscal year of the American Medical Association is from January 1 to December 31; and the annual dues paid by a new member cover only the fiscal year, no matter at what time of year the membership is obtained. Those who pay their dues and join the Association at the annual meeting in June, for instance, pay only for the fiscal year which ends with the December following, and the annual dues for the following fiscal year are payable the succeeding January, at which time the treasurer sends a statement to each member. Such members, however, are entitled to The Journal for the full year, even though the membership be not continued.

PAPERS READ AT THE ANNUAL MEETING.

"Every paper received by this Association and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the Association. . . The Board of Trustees shall have full discretionary power to omit from the published transactions, in part or in whole, any paper that may be referred to it by the Association or either of the Sections, unless specially instructed to the contrary by vote of the Association." (From Article V of the By-laws.)

NEWS.

Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

ORIGINAL PAPERS.

Articles are accepted for publication with the understanding that they are contributed solely to this journal.

COPYRIGHT.

Matter appearing in The Journal of the American Medical Association is covered by copyright, but as a general thing, no objection will be made to the reproduction of anything appearing in its columns if proper credit be given.

CONTRIBUTIONS TYPEWRITTEN.

It will be satisfactory to all concerned if authors will have their contributions typewritten before submitting them for publication. The expense is small to the author—the satisfaction is great to the editor and printer. We can not promise to return unused manuscript.

Half-tones, zinc etchings and other illustrations will be furnished by The Journal when photographs or drawings are supplied by the author.

ADVERTISEMENTS.

Advertising forms go to press eight days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. Advertising rates will be made known on request.

CHANGE OF ADDRESS.

In ordering a change of address it is important that both the old and new addresses be given.

REMITTANCES.

Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "Journal American Medical Association," except those for annual dues. These should be made payable and sent direct to the Treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago.

Vol. XXXVI. CHICAGO, ILLINOIS, JANUARY 12, 1901. No. 2.

Original Articles.

THE DIAGNOSIS AND TREATMENT OF THE PREBACILLARY STAGE OF PULMONARY TUBERCULOSIS.*

J. M. ANDERS, M.D., LL.D.
PHILADELPHIA.

By the title of this article is meant that variable period in pulmonary tuberculosis which precedes the presence of tubercle bacilli in the sputum. It is not synonymous with the term "pretubercular stage," which has reference either to an inherited or acquired predisposition merely, or to a latent tuberculous process. The prebacillary stage, as here defined, is oftimes of long duration. Concerning the stage of enclosure Allbutt[1] observes that an examination of the sputum can not help us decisively in tuberculous endobronchitis. In my own experience the bacilli were sometimes not found in the sputum for months, or even a year, after the apparent onset. Turban[2] examined the sputum in the first stage in 408 cases and failed to find tubercle bacilli in 59.8 per cent.

It may be safely affirmed, then, that an antecedent well-characterized clinical stage is often observed. Eichhorst[3] forcibly remarks, "Certainly one finds off and on undoubted cases of pulmonary tuberculosis in which tubercle bacilli are missed, a daily examination of the sputum notwithstanding." It must be conceded that unless other methods of diagnosticating pulmonary tuberculosis than the demonstration of tubercle bacilli in the sputum be resorted to, not a small minority of cases would go unrecognized, some for months, or even a year, and some forever.

While emphasizing this class of cases, it is not my desire to attempt to shake professional trust in the sputum-test, which in the majority of cases, perhaps, enables clinicians to form a positive diagnosis at an early stage of the disease and in cases not otherwise solvable, but on the other hand, to urge that it be repeated at short intervals in clinically suspicious cases. Percy Kidd[4] has indicated certain clinical groups of cases in which the true nature of the complaint may be masked by a generalized bronchitis, or laryngitis and the like, in which a sputum examination yields the earliest positive information.

I am relieved of the necessity of dwelling at length on many of the more remote early manifestations of the disease by reason of the elaborate and accurate descriptive writings of Ruehle,[5] Sée,[6] and others. Brief attention, however, will be invited to the practical points bearing on diagnosis that have been emphasized by some of the older writers and the value of which personal observation and experience has tended to corroborate and strengthen.

Heredity.—The influence of heredity is still incontrovertible, although less potential than was held previous to Koch's startling and revolutionizing discovery. Whilst the progeny of tuberculous parents often suffer, it is, as a rule, owing to an extrauterine or post-fetal infection, direct transmission being the exception. G. Hauser,[7] after reviewing at length the work of previous writers on direct inheritance, reaches the conclusion that there are but 18 authentic instances on record. He declares that the theory of the bacillary inheritance of tuberculosis rests on insufficient evidence. But, though intrauterine infection is extremely rare, and though there is practically no hereditary tuberculosis, there is a hereditary predisposition which invites infection. Hence, a somewhat different rôle, although one of considerable importance, is assigned to heredity. We are not concerned at present writing with the many evident methods of infection that may be operative from the time of birth and cause so striking a similarity between post-natal and ante-natal tuberculosis. This fact, however, coupled with the long period of latency of tuberculosis in childhood, must be recollected in deciding from the appearance of an individual, first, whether he has the habitus phthisicus, and secondly, whether it is really inherited. For example, as the result of an unfavorable environment, particularly if combined with bad habits, this predisposition may be acquired. E. O. Otis[8] pertinently affirms that heredity *means poor* vitality from birth and that subjects who manifest the same conditions without the influence of heredity are predisposed to a like extent. I have, however, frequently been able to satisfy myself that individuals possessing a *robust* build are, if they belong to affected families, more prone to the disease than apparently similar constitutions in persons who have no tuberculous family history. Indeed, I fear that in consequence of the modification of professional opinion in recent times relative to the question of heredity there is danger that too little attention is now, and will be in future, given to the family history.

The point of greatest practical importance is that the immigration and lodgment of bacilli are distinctly favored in a predisposed organism as compared with one that is perfectly normal; hence, this hereditary influence, when clearly present, is not only of etiologic but also of diagnostic importance. Allbutt[1] says: "Every physician engaged in practice among the classes in which family history can be acquired is morally convinced of the bias of many families to tuberculosis, however healthy their circumstances may appear; a bias often revealed in each of their members on the attainment of a certain age."

The personal history, however, surpasses in point of import the family history. The age of the patient is

Brazil: Pernambuco, Nov. 15, 16 deaths; Rio de Janeiro, Oct. 16-31, 43 deaths.
Egypt: Alexandria, Nov. 27, 3 cases, 1 death.
England: London, Nov. 24-Dec. 1, 14 cases, 1 death; Sunderland, Dec. 1, 1 case.
France: Paris, Dec. 1, 17 deaths.
Gibraltar: Nov. 25, 1 case.
Greece: Athens, Dec. 1, 2 cases.
India: Calcutta, Nov. 3-15, 8 deaths.
Mexico: Mexico, Dec. 2, 1 case; Tuxpan, Dec. 3-10, 3 deaths
Russia: Moscow, Nov. 17-24, 3 cases, 1 death; Odessa, Nov. 24, 62 cases, 15 deaths; St. Petersburg, Nov. 24, 5 cases, 2 deaths; Warsaw, Nov. 24, 25 deaths.
Scotland: Glasgow, Dec. 7, 45 cases, 1 death.
Spain: Corunna, Nov. 3, 2 deaths; Valencia, Dec. 2, 1 case.

YELLOW FEVER.

Brazil: Rio de Janeiro, Oct. 16-31, 2 deaths.
Mexico: Vera Cruz, Dec. 8, 2 deaths; Yucatan, Nov. 30, 1 death.

CHOLERA.

India: Bombay, Nov. 13-20, 7 deaths; Calcutta, Nov. 3-15, 35 deaths; Madras, Nov. 10-16, 2 cases, 1 death.
Straits Settlements: Singapore, Nov. 3, 6 deaths.

PLAGUE—FOREIGN AND INSULAR.

Brazil: Rio de Janeiro, Oct. 16-31, 9 deaths.
India: Bombay, Nov. 13-20, 125 deaths; Madras, Nov. 10-16, 1 death.
Philippine Islands: Manila, Nov. 3, 3 cases, 1 death.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage, $2.50. Subscriptions may commence at any time. Volumes begin with the first issue of January and of July.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

The qualifications for membership require that the applicant be a member, in good standing, of a state or local medical society entitled to send delegates to the annual meeting of the American Medical Association. A list of these societies will be sent on request. Applications must be accompanied with a certificate showing that the applicant is a member of a recognized society, and should be sent with the annual dues—five dollars—to the treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago. Members receive The Journal free. Subscribers to The Journal may become members of the Association without additional expense if they are members of medical societies recognized by the Association. Those desiring to have their names transferred from the subscription to the membership lists should send certificates as above, with a receipt for their subscription to The Journal, covering the current fiscal year.

FISCAL YEAR.

The fiscal year of the American Medical Association is from January 1 to December 31; and the annual dues paid by a new member cover only the fiscal year, no matter at what time of year the membership is obtained. Those who pay their dues and join the Association at the annual meeting in June, for instance, pay only for the fiscal year which ends with the December following, and the annual dues for the following fiscal year are payable the succeeding January, at which time the treasurer sends a statement to each member. Such members, however, are entitled to The Journal for the full year, even though the membership be not continued.

PAPERS READ AT THE ANNUAL MEETING.

"Every paper received by this Association and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the Association. . . The Board of Trustees shall have full discretionary power to omit from the published transactions, in part or in whole, any paper that may be referred to it by the Association or either of the Sections, unless specially instructed to the contrary by vote of the Association." (From Article V of the By-laws.)

NEWS.

Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

ORIGINAL PAPERS.

Articles are accepted for publication with the understanding that they are contributed solely to this journal.

COPYRIGHT.

Matter appearing in The Journal of the American Medical Association is covered by copyright, but as a general thing, no objection will be made to the reproduction of anything appearing in its columns if proper credit be given.

CONTRIBUTIONS TYPEWRITTEN.

It will be satisfactory to all concerned if authors will have their contributions typewritten before submitting them for publication. The expense is small to the author—the satisfaction is great to the editor and printer. We can not promise to return unused manuscript.

Half-tones, zinc etchings and other illustrations will be furnished by The Journal when photographs or drawings are supplied by the author.

ADVERTISEMENTS.

Advertising forms go to press eight days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. Advertising rates will be made known on request.

CHANGE OF ADDRESS.

In ordering a change of address it is important that both the old and new addresses be given.

REMITTANCES.

Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "Journal American Medical Association," except those for annual dues. These should be made payable and sent direct to the Treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago.

Original Articles.

THE DIAGNOSIS AND TREATMENT OF THE PREBACILLARY STAGE OF PULMONARY TUBERCULOSIS.*

J. M. ANDERS, M.D., LL.D.
PHILADELPHIA.

By the title of this article is meant that variable period in pulmonary tuberculosis which precedes the presence of tubercle bacilli in the sputum. It is not synonymous with the term "pretubercular stage," which has reference either to an inherited or acquired predisposition merely, or to a latent tuberculous process. The prebacillary stage, as here defined, is oftimes of long duration. Concerning the stage of enclosure Allbutt[1] observes that an examination of the sputum can not help us decisively in tuberculous endobronchitis. In my own experience the bacilli were sometimes not found in the sputum for months, or even a year, after the apparent onset. Turban[2] examined the sputum in the first stage in 408 cases and failed to find tubercle bacilli in 59.8 per cent.

It may be safely affirmed, then, that an antecedent well-characterized clinical stage is often observed. Eichhorst[3] forcibly remarks, "Certainly one finds off and on undoubted cases of pulmonary tuberculosis in which tubercle bacilli are missed, a daily examination of the sputum notwithstanding." It must be conceded that unless other methods of diagnosticating pulmonary tuberculosis than the demonstration of tubercle bacilli in the sputum be resorted to, not a small minority of cases would go unrecognized, some for months, or even a year, and some forever.

While emphasizing this class of cases, it is not my desire to attempt to shake professional trust in the sputum-test, which in the majority of cases, perhaps, enables clinicians to form a positive diagnosis at an early stage of the disease and in cases not otherwise solvable, but on the other hand, to urge that it be repeated at short intervals in clinically suspicious cases. Percy Kidd[4] has indicated certain clinical groups of cases in which the true nature of the complaint may be masked by a generalized bronchitis, or laryngitis and the like, in which a sputum examination yields the earliest positive information.

I am relieved of the necessity of dwelling at length on many of the more remote early manifestations of the disease by reason of the elaborate and accurate descriptive writings of Ruehle,[5] Sée,[6] and others. Brief attention, however, will be invited to the practical points bearing on diagnosis that have been emphasized by some of the older writers and the value of which personal observation and experience has tended to corroborate and strengthen.

Heredity.—The influence of heredity is still incontrovertible, although less potential than was held previous to Koch's startling and revolutionizing discovery. Whilst the progeny of tuberculous parents often suffer, it is, as a rule, owing to an extrauterine or post-fetal infection, direct transmission being the exception. G. Hauser,[7] after reviewing at length the work of previous writers on direct inheritance, reaches the conclusion that there are but 18 authentic instances on record. He declares that the theory of the bacillary inheritance of tuberculosis rests on insufficient evidence. But, though intrauterine infection is extremely rare, and though there is practically no hereditary tuberculosis, there is a hereditary predisposition which invites infection. Hence, a somewhat different rôle, although one of considerable importance, is assigned to heredity. We are not concerned at present writing with the many evident methods of infection that may be operative from the time of birth and cause so striking a similarity between post-natal and ante-natal tuberculosis. This fact, however, coupled with the long period of latency of tuberculosis in childhood, must be recollected in deciding from the appearance of an individual, first, whether he has the habitus phthisicus, and secondly, whether it is really inherited. For example, as the result of an unfavorable environment, particularly if combined with bad habits, this predisposition may be acquired.—E. O. Otis[8] pertinently affirms that heredity means poor vitality from birth and that subjects who manifest the same conditions without the influence of heredity are predisposed to a like extent. I have, however, frequently been able to satisfy myself that individuals possessing a robust build are, if they belong to affected families, more prone to the disease than apparently similar constitutions in persons who have no tuberculous family history. Indeed, I fear that in consequence of the modification of professional opinion in recent times relative to the question of heredity there is danger that too little attention is now, and will be in future, given to the family history.

The point of greatest practical importance is that the immigration and lodgment of bacilli are distinctly favored in a predisposed organism as compared with one that is perfectly normal; hence, this hereditary influence, when clearly present, is not only of etiologic but also of diagnostic importance. Allbutt[1] says: "Every physician engaged in practice among the classes in which family history can be acquired is morally convinced of the bias of many families to tuberculosis, however healthy their circumstances may appear; a bias often revealed in each of their members on the attainment of a certain age."

The personal history, however, surpasses in point of import the family history. The age of the patient is worthy of consideration, and the fact that the disease is not uncommon in middle or even advanced life must be recollected. Since the increased prevalence of influenza, dating from the winter of 1889-90, senile phthisis has become more common than it had been previously. The occupation, station, loss of weight and various details connected with the previous environment must be carefully noted and judiciously weighed. Knopf[9] has very properly emphasized the importance of determining whether the patient ever came into direct, prolonged contact with a consumptive or a patient suffering from bronchial pulmonary disease.

---

* Presented in a Symposium on Tuberculosis, to the Section on Practice of Medicine, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Physical Examination.—The paralytic thorax is generally in evidence during the initial stage of pulmonary tuberculosis and should be looked on as the resultant of an incipient tuberculous process in the majority of cases rather than an antecedent condition. It must not, however, be confounded with an extreme emaciation nor the deformity which simulates it, due to occupation, as habitually leaning over a desk, and the like. Conversely, the flattened chest, with its short antero-posterior diameter (paralytic thorax), may be concealed in subjects of obesity during the incipient stage. I am in thorough agreement with Loomis[10] that the data obtained by measuring the circumference of the chest are more important than its shape. This thoracic perimeter, which represents two measurements, one at the end of forced expiration and the other of forced inspiration, should never fall below one-half the height of the individual. It has been shown that when the thoracic perimeter is lower than this, early phthisis exists, although this may assume a latent form. In connection with the phthisical thorax and chest measurements, the vital capacity as determined by the spirometer, is of confirmatory value in diagnosis, particularly when considered in relation to the height. This method is fully described by Loomis,[10] to whose article I must refer the Section for detailed information.

Preceding the finding of bacilli in the expectoration, obvious physical signs, variable in character, are quite commonly met with, and may endure for weeks, or even months, ere the diagnosis is set at absolute rest by the stage of the microscope. These abnormities are first detected in the subapical regions, and in my cases they have occurred posteriorly in, perhaps, the majority of instances. Turban wisely remarks that "The scapula must be abducted by drawing the arm across the chest, so as to give access to the cage of the chest between its edge and the spine." He also states that light and single percussion must be used. I have for years given preference to single as compared with multiple blows in early cases in which it was desired to outline minute consolidated areas. I have also frequently convinced myself of the practical importance of percussing every inch of ground when a search for the primary lesions in the usual situation (subapical area) gives a negative result. Among the earliest and perhaps the most significant signs is the diminution or almost total loss of the normal vesicular murmur. To test the strength or weakness of the vesicular quality of the murmur, the corresponding regions on the two sides must be invariably compared, both during quiet and deep breathing. Coupled with or following on enfeeblement of the normal vesicular murmur, prolongation and sharpening of the expiration are generally noted. The tactile fremitus may also be increased, but this is often absent on account of associated pleurisy. I regard defective expansion at or a little below one apex as profoundly significant, particularly if observed in the infraclavicular spaces, and in some of my cases "lagging" was the first and for a considerable period of time the only recognizable physical sign. It is best appreciated by palpation. The most characteristic grouping of physical signs during the first stage—sometimes in evidence prior to the discovery of tubercle bacilli—may be thus summarized: "Lagging," or defective expansion, as noted in inspection and palpation, a localized increase in the tactile fremitus, enfeeblement of the normal vesicular murmur with (at a later period) prolongation and sharpening of the expiration. To the signs mentioned above should be added a clicking râle, which, though less commonly present, is an almost conclusive indication.

The percussion note may be impaired or deadened, but this sign is quite unreliable in the earliest period, becoming more trustworthy, however, as consolidation progresses. A pleuritic friction sound may be rarely heard in the apical area; it is usually dependent on the tuberculous process. Later crepitant and subcrepitant râles (moist sounds) are heard, and greatly increase the probability that tuberculous infiltration has taken place. Among other suggestive, invasive symptoms and conditions are:

1. Pleurisy. This may take the form of serofibrinous pleurisy, inasmuch as about one-third of these cases terminate in chronic phthisis—Bowditch. It may also assume the guise of a dry pleurisy at the apex, either anteriorly or posteriorly.

2. Gastrointestinal symptoms, with chloro-anemia. The digestion is impaired; there is a rapid loss of flesh and strength, and an afternoon rise of temperature, with pronounced anemia. This grouping of features (chloro-anemia) is often followed by the appearance of the earlier positive indications of pulmonary tuberculosis.

3. Hemoptysis. This may be the first symptom to excite suspicion of lung disease. In many of these cases a typical picture of incipient pulmonary tuberculosis is found on examination, and they may pursue the usual course, showing that a slight tuberculous lesion was an antecedent condition. I would here throw out the caution that all other causes for the spitting of blood should be carefully excluded, unless the evidences of commencing phthisis are conclusive at the time of the occurrence of the primary hemorrhage.

4. Onset with symptoms of laryngitis. Although rare, there are cases occasionally met, characterized by hoarseness, aphonia and troublesome cough, with a slight mucopurulent expectoration. The bacilli may be found in the sputum before any lesions of the lungs are discoverable. C. N. Haskell[11] regards headaches and indigestion as two of the most important remote symptoms of consumption. Two cases were recently met in my own experience that tend to strengthen the view expressed by this observer.

The clinical evidences of commencing phthisis mentioned above justify a probable diagnosis; they are diagnostic aids, and if two or more are found in combination, as is usual, should be regarded as presenting the therapeutic indications of this affection. It has been argued that the physical signs furnish the basis of an assured diagnosis. While it must be conceded that the physical signs enable a keen observer to recognize with reasonable certainty the existence of phthisis—at times before all doubt is removed by the stage of the microscope—it is even more true that once these signs disclose the presence of pulmonary tuberculosis, the disease has passed beyond the incipient stage as this term is understood at present writing.

The presence of a slight afternoon rise of temperature, if associated with either local or general disturbance, should arouse strong suspicion, since it would be difficult to overestimate the diagnostic importance of this symptom.

A two-hourly thermometric record must be kept during the entire day, for several days together, or the rise of temperature may elude detection. Barlow states that if the temperature is elevated from 2 to 5 degrees p.m., or one slightly above the normal night temperature in the evening, the probabilities are greatly in favor of tuberculosis. Trudeau[12] points out that when any disturbance of health exists, and the evening temperature runs above 99.5 F., there is almost surely tuberculosis present. Turban[2], among recent writers, also believes frequent thermometric estimations of the temperature to be extremely helpful. He urges to test the temperature after exertion, taking between 4 and 6 o'clock in the afternoon, if doubt remains as to the presence of fever. Louis long since asserted that fever starts in a third of the cases with the first local symptoms, and even before then; in another fifth of the cases it is manifested in the course of the first period. Sydney Ringer[13] points out that the exacerbation of fever coincides with the evening elevation which takes place normally, and that it is now characterized by an acceleration of the pulse, which makes the fever appear more intense than it is in reality.

Sée[6] observes that the application of the thermometer permits us to distinguish this state from chlorosis, "which but rarely provokes a like excitement of the heart and never hyperthermia." Fever may be present for a long period of time before the sputum-test gives a positive result. On the other hand, as Makenzie[15] asserts, in cases with a fair number of bacilli in the expectoration, the temperature may be for weeks perfectly normal. It is a matter of congratulation that from the standpoint of temperature a reasonably certain diagnosis is easily possible and also that the profession is not divided at present in regard to this question. Here may be pointed out, what is well understood, that an intermittent fever simulating that of malaria is not rarely seen in tuberculosis at its commencement. It is distinguished from malarial fever only by a careful blood examination, which shows the absence of the plasmodium. Even an elevation of temperature due to other causes, such as anemia, suppuration and the like, is also easily eliminated by a blood examination.

A quickened pulse is often present at the outset, preceding the appearance of bacilli in the sputum by weeks and even months, and it is suggestive, although less so than the brief afternoon febrile movement. On the other hand, certain observers claim that the pulse in early phthisis is characteristic. According to my observations, the heart-beat is not constantly accelerated at this period. I have, however, observed that a rapid, feeble pulse is one of the almost unvarying features of early phthisis in the very young. When at this period of life the pulse has been found rapid and feeble, it has served in my experience to corroborate strongly the diagnosis. Knopf states that taking the "arterial pressure with the aid of Potain's sphygmomanometer is a most valuable help in diagnosing an early pulmonary tuberculosis." The instrument enables one to easily determine the arterial pressure of the patient; this is usually diminished, as shown by Papillon's recent examination in Potain's service at the Charité in Paris.

E. F. Wells[15] has found the arterial tension to be early and notably reduced, especially during the febrile exacerbations; he has met with no exceptions to this rule. This writer holds that "sphygmographic tracings give most valuable aid in the diagnosis of early pulmonary tuberculosis, and from these alone the scale may be turned in the great majority of doubtful cases." He illustrates with tracings which show a pulse of lower tension and infantile character. From this "typical curve there are infinite variations in both directions, approaching the normal on the one hand and reaching the most pronounced dicrotism on the other." It is precisely on account of the extreme variability of the arterial tension that I can assign merely a high confirmatory value to the pulse. On the other hand, R. Grandin[16] claims that the arterial pressure varies, being sometimes increased, sometimes decreased. I have been able to verify DaCosta's original observation, that a murmur is sometimes audible over the subclavian or pulmonary artery before either physical signs referable to the lungs are detectable or fever occurs. In three of my cases, abnormal conduction of the cardiac sounds preceded the detection of the usual earliest signs of commencing consolidation—two in left-sided and one in right-sided pulmonary tuberculosis. In all of them tubercle bacilli were subsequently found in the expectoration, and since all were observed within the last year, this sign may on receiving greater attention prove to be more profoundly significant as a diagnostic factor than when, as is usual, it occurs at a later period. In one of my cases this was the only clinical indication that aroused suspicion that the disease might be developing, apart from slight, dry cough that had lasted a couple of weeks.

The Tuberculin Test.—This enables the physician to clear the nature of latent forms and dubious cases, however incipient; its value depends principally on the fact that it permits of the recognition of the disease before its presence can be otherwise determined. As showing the value of the tuberculin test for the early diagnosis of pulmonary tuberculosis, I will in the first place cite three cases that were recently met in my practice and reported elsewhere.[17] The first occurred in a lad aged 14, who had always been in delicate health. The illness for which he consulted me had commenced four weeks previously with symptoms that were distinctly typhoidal in character, and later a positive Widal reaction was obtained. A physical examination at my first visit revealed only a phthisical thorax. After the fever had declined an injection of tuberculin (2 mg.) gave a positive reaction. An X-ray photograph was then taken, and showed slight, though decisive, haziness.

The second case was one of suspected acute tuberculosis. The diagnosis was confirmed by the tuberculin test. The necropsy was held six weeks later by Dr. MacFarland, who found miliary tuberculosis following Pott's disease, with beginning psoas abscess. He found, it is interesting to note, "each tubercle surrounded by a zone of hyperemic vessels, which gave it a dark bluish-purple color," and observed also that its center was softened and depressed.

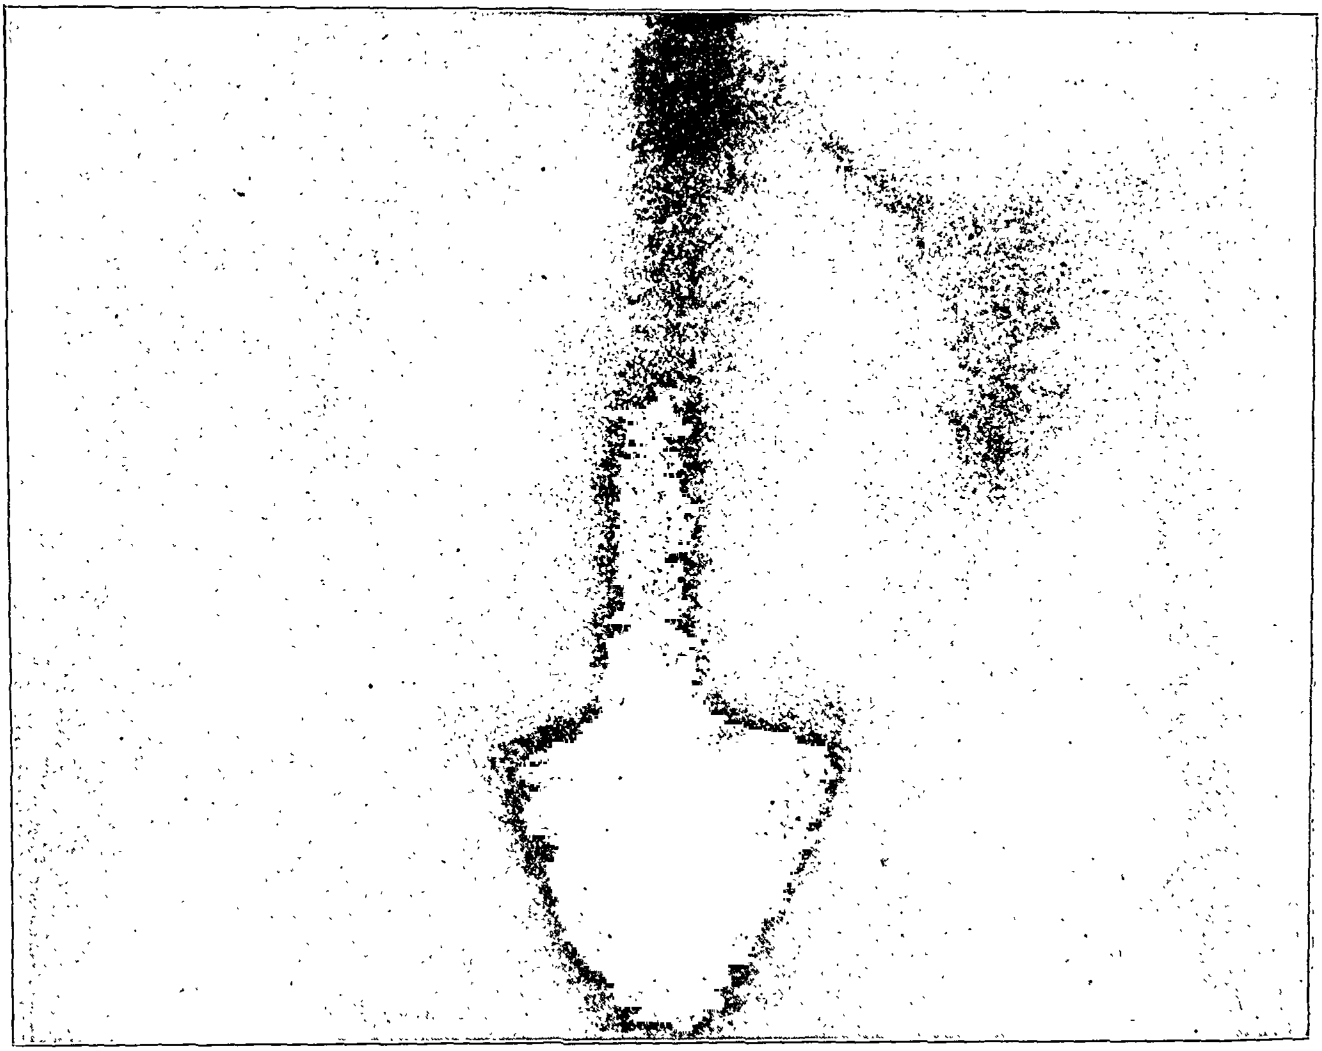
My third case occurred in J. H., aged 19 years, occupation, laborer; he was admitted to the wards of the Medico-Chirurgical Hospital, Jan. 2, 1900. There was no history of family tuberculous taint, and the patient had enjoyed good health until February, 1899, when he took a severe cold, following upon which he continued to cough until the onset of the illness for which he applied. On December 30, while stooping to lift a heavy weight, he suddenly experienced a warm saline taste, which suddenly led to cough, accompanied by the expectoration of a small amount of bright red, frothy blood. Physical examination showed nothing save a few subcrepitant râles in left scapular region. Both fluoroscopic examination of the thorax and repeated microscopic examination of the sputum gave a negative result. On the other hand, an injection of tuberculin (1 mg.) responded positively. The patient's sputum afterward showed the presence of tubercle bacilli.

There is little if any diversity of professional opinion among those who have had considerable experience with the tuberculin test as to its diagnostic value when judiciously employed. As pointed out in a previous article, "its use for diagnostic purposes has been condemned by writers who, almost without exception, failed to avail themselves of an opportunity to make a practical test."

I am deeply impressed with the belief, from a limited experience only, that its more general employment, with judicious care, would re-establish its superior value, in properly selected incipient cases. Among those writers who are entitled to be heard and who have spoken in no uncertain tones in favor of tuberculin as a diagnostic agent in tuberculosis are J. T. Whittaker,[18], M. Beck,[19] E. L. Trudeau,[20] F. W. White,[21] A. C. Klebs,[22] G. G. Sears,[21] E. O. Otis,[23] *Von Jaksch,*[24] *and others.*

I have prepared two tables, which appear in my article (to which reference has been made above), Table No. 1 showing the total number of cases that have been injected with tuberculin—3638—the total number of positive reactions—2185, or 78 per cent.—and the dosage and particular preparation employed by different observers. With a view to obtaining greater accuracy of results, a consideration of the character of the cases at the time of the injections was deemed necessary, and this method was adopted in Table No. 2, which sets forth the figures indicating how many were doubtful and how many undoubted instances of the disease at the time of injection, with the percentage of reactions of each respectively.

In 1470 dubious cases, 71.89 per cent. reacted. What percentage of these cases subsequently developed a confirmed tuberculosis, or the percentage in which the diagnosis was corroborated by necropsy, can not be even approximately told. During my collective investigations, however, I found that writers who had experience with Koch's method referred to individual cases that either came to autopsy and showed tuberculous foci or later manifested the obvious signs and symptoms of the disease. Of the three cases which I recorded above, two were similarly verified, one at the autopsy table, and the other by the detection of tubercle bacilli in the sputum. I have employed tuberculin in 12 suspicious cases, of which 7, or 58.3 per cent., reacted. Is the tuberculin test attended with any risks for the patient? It must be confessed that there is a prevalent impression that tuberculin injections facilitate the diffusion of the bacilli in the system. Virchow,[25] who originally promulgated this view and whose published argument based on his-



Case 1.

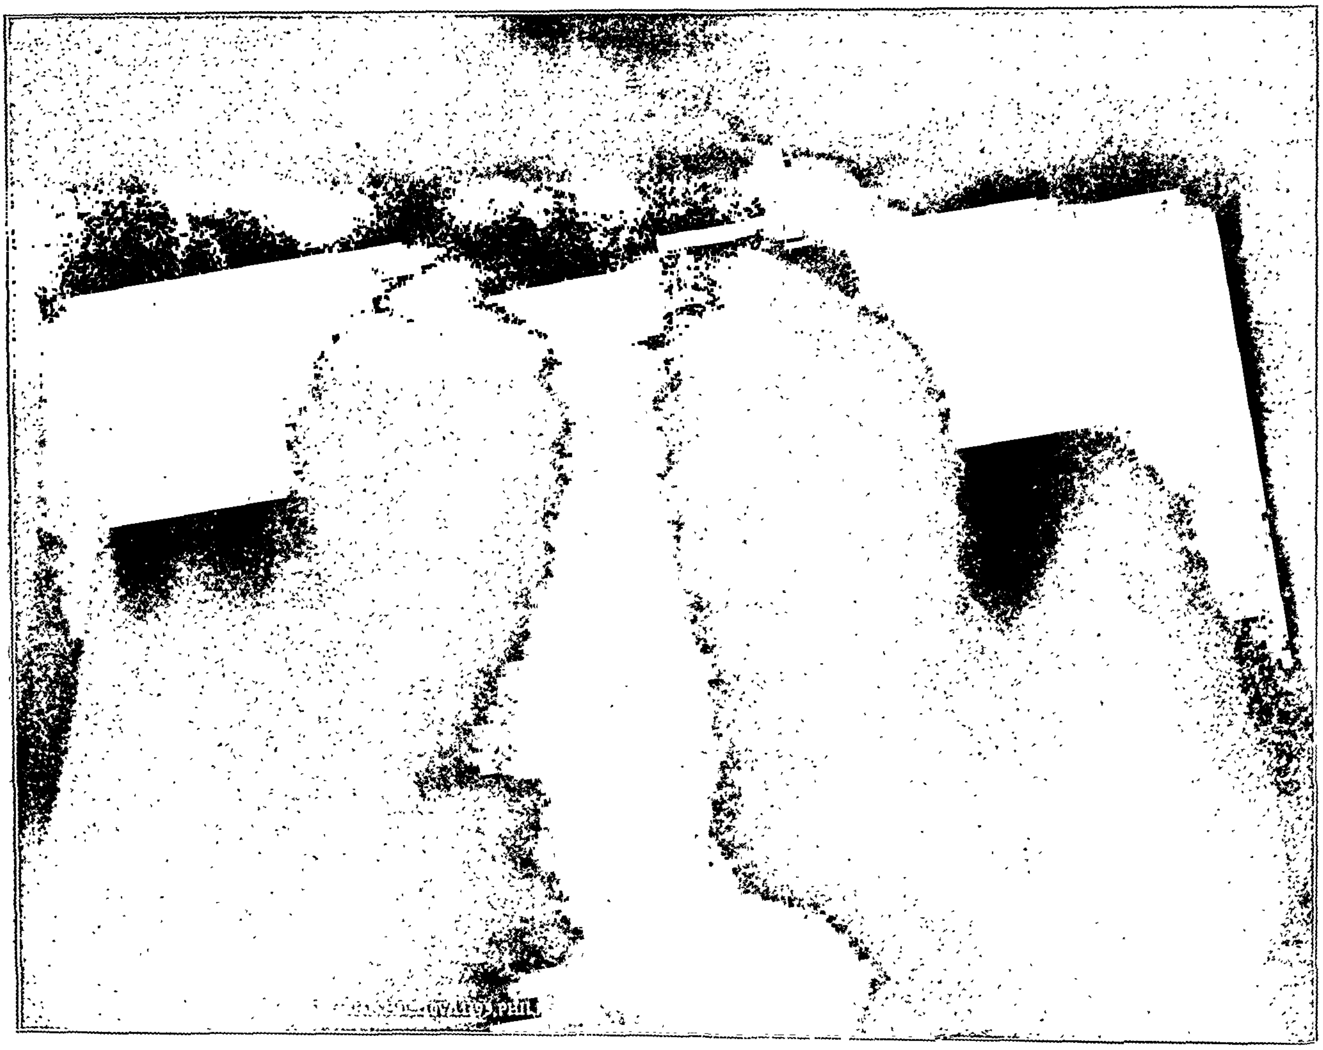
tologic and pathologic data caused tuberculin to fall into almost universal disrepute, has quite recently receded from his former position, and he now approves of Koch's method in selected cases. It is worthy of note that in not a single series of cases among the many included in the tables which I have prepared is mention made of any ill effects. At all events, I have not met a solitary authentic report of a case in which the disease has been disseminated to distant parts of the economy with ensuing acute tuberculosis.

Numerous observers have noted reactions in the so-called non-tuberculous subjects and in individuals suffering from other affections. They have been obtained in leprosy, carcinoma, syphilis, actinomycosis, chlorosis and other affections, as well as in 8 or 9 per cent. of apparently healthy individuals. In reactive cases of this sort, however, unsuspected foci may exist.

The dose and the particular class of cases to which the tuberculin is applicable are questions that demand careful consideration. As elsewhere pointed out, "tuberculin will tend to occupy its true sphere of usefulness just in proportion as the profession will in future keep in mind two rules as a guide, to wit, moderate dosage—mg. 2 to 5—and the limitation of its use to suspicious incipient cases, or those that are unrecognizable by other means." It is to be recollected that early, suspected cases are as a rule sensitive to the test and massive doses are not required.

The symptoms to be expected from a reaction are malaise, general depression, anorexia, headache, pain in the back and limbs, sensation of heat and cold, followed by sweating and an elevation of temperature to 101 F., or over. The reaction usually occurs in about 12 hours, rarely as late as 24 hours, and continues from 24 to 48 hours. If no reaction follows the first injection, a larger dose—up to mg. 10—should be used, but not until after the lapse of several days. As forcibly pointed out by Wells,[16] "in the tuberculin test a negative result is of great importance, because, if the observations have been carefully made, we may affirm that not only is the suspected pulmonary affection not tubercular, but that there are no latent pulmonary foci and that tuberculosis does not exist in other parts of the body."

Among the most valuable agencies for the early diagnosis of pulmonary tuberculosis are the Roentgen rays. In phthisis these radioscopic appearances are usually observed in the subapical regions, and they sometimes show the presence of tuberculous infiltration and consolidated areas before either the physical signs are obvious or the microscopic slide demonstrates the tubercle bacilli in the sputum. It is doubtless true that reliable knowledge from the use of the Roentgen rays and fluoroscope is possible only to an expert or an experienced observer. Again, the value of this means of recognizing pulmonary tuberculosis in its first stage would be greatly increased, if the images shown by the fluoroscope could be satisfactorily photographed in all cases. Francis H. Williams[20] states that he has discovered radioscopic evidences of consolidation before physical signs of such change were present; also that he has found indications of the



CASE 2.

istence of tuberculosis when this disease had not been suspected previously. Stubbert[27] has also reported one or two instances in which "slight haziness has been observed in spots which at the time showed no other physical signs of disease, but where they subsequently developed."

The practical utility of the X-rays in the diagnosis of incipient pulmonary tuberculosis may be further illustrated by the notes of the following cases that fell under my care:

CASE 1.—S. H., female, married, age 28 years, cigar-maker, first applied at the outpatient clinic of the Medico-Chirurgical Hospital, June 6, 1899, for treatment. A brother died of acute phthisis. Patient had had some childish disease, but later in life nothing worthy of comment until the onset of the disease for which she sought medical advice. Her illness began with paroxysmal pains in precordia, and this lasted for a considerable period of time. The day previous to her visit, she had expectorated blood, which she states was "coughed up"; quantity of blood was small, bright-red and frothy. The abnormal physical signs were impairment of percussion-note and harsh breathing, with prolonged, high-pitched expiration at right apex; and lack of vesicular quality of the breath sounds, with prolonged, high-pitched expiration at left apex; all signs, however, were less marked than at right apex. Microscopic examination of the sputum gave a negative result. Later, an X-ray examination showed an abnormal shadow or marked haziness at apex of both lungs, more marked at right, i. e., the apex that showed the abnormal signs the more pronounced. (See Fig. 1.)

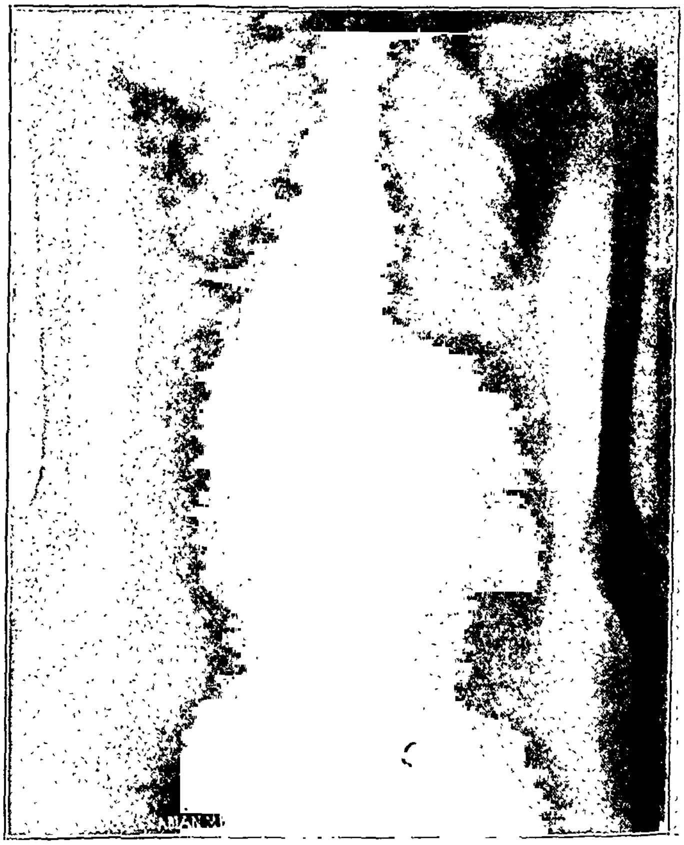
CASE 2.—P. K., age 29 years, cigar-maker, applied for treatment at outpatient clinic, November 10, 1899. The family history is entirely negative as to pulmonary tuberculosis. Patient escaped childish diseases; he had had typhoid fever one and a half years previously, confining him to bed for ten weeks. Since then has been complaining of persistent gastric disturbance, as evidenced by eructations of gas and dull pains in the epigastrium after meals; there has been some dyspnea on exertion and cardiac palpitation at intervals. A few days prior to his first visit, patient began to expectorate bright-red blood; this was still present. Subsequently there was neither cough nor expectoration. The amount of blood lost did not exceed half an ounce. An examination of the throat and larynx gave a negative result, and the same was true of a physical examination of the thorax, although the chest was of the paralytic or phthisical type. After excluding all the causes of hemoptysis except pulmonary tuberculosis, an X-ray picture was made by Dr. Kassabian. This showed commencing consolidation over circumscribed areas on both sides just below the apices. (See Fig. 2.)

CASE 3.—J. O., age 14 years, errand-boy, was admitted to the wards of the Medico-Chirurgical Hospital, November 13, 1899. Father died, aged 52 years, of heart and lung disease, the precise nature of which the patient does not know. One sister is in delicate health. The lad had had the usual diseases of childhood and a severe illness of unknown character a few years since; had always been in delicate health. The present illness began about four weeks before he fell under my observation. The first symptoms complained of were malaise, headache, a slight cough in the evenings and mornings; more or less abdominal pain, associated with slight diarrhea. The evening temperature on admission was on the average about 100 F., but abdominal pain, diarrhea and cough had largely subsided. Physical examination showed a paralytic or phthisical thorax, without any other abnormal physical signs. After excluding typhoid fever, latent tuberculosis was suspected, and tuberculin was injected; this was followed by a positive reaction. An X-ray examination was also made by Dr. Kassabian and showed a slight haziness below the left clavicle. (See Fig. 3.)

Whether or not this patient will develop the more active and obvious lesions of the disease remains to be seen.

CASE 4.—M. B., female, age 17 years, colored, American, housework; fell under the care of Dr. A. E. Blackburn at the outpatient clinic of the Presbyterian Hospital, September 7, 1898. The family history was indefinite; the mother deceased, but cause of death unknown. Patient had had measles in childhood, otherwise the previous history was negative.

Present illness began three years ago with cough and expectoration; these symptoms had persisted until she applied for relief, there was no loss of flesh and no night-sweats. Physical signs at time of first visit: defective expansion, increased tactile fremitus, impaired percussion resonance and increased vocal resonance over right apex, anteriorly, and left apex normal. On November 3, no tubercle bacilli were found: they were found, however, on February 10, 1899. Dulness on percussion and prolonged expiration over right apex. March 30 moist râles at both apices, more marked at right. June 8, beginning cavity formation in right lung at third rib. August 17, signs of cavity well marked in right chest. Photograph of fluoroscopic plate shows a distinct shadow extending from right apex to fourth rib. There is no rare area or bright spot to indicate the presence of a cavity.



CASE 3.

This may have been due to the superimposed dense area occasioned by the thick cavity-wall and pleura; again the cavity may have been filled or nearly so with secretion to account for the absence of the rarer area or bright spot. I regret that the patient had not been minutely examined just prior to the use of the Roentgen rays. The last case reported above (Case 4) can not be classed as an incipient one, but is included because of its great interest, as showing a source of fallacy in skiagraphy in the stage of cavity. The agglutinative reaction is as yet without diagnostic value.

The principal object of this paper is to indicate the comparative infrequency of the presence of tubercle bacilli or of clear physical signs as keys to the situation in the commencing stage. It is obvious that physicians should more generally make use of other aids on which a diagnosis sufficiently accurate for practical purposes could be made, thus affording a basis of therapeutic and climatic indications while the disease is yet amenable to treatment. Among the means previously described, I would re-enumerate points relating to causation, including heredity and the numerous circumstances that expose an individual to infection, and the varied manifestations of the disease at the very onset—embraced under the rarer modes of invasion—described above. A not uncommon association is to find in subjects hereditarily predisposed or thrown into prolonged contact with a consumptive, the later development of suspicious features, which have been grouped above under various heads. The commonest group includes those cases in which a suggestive history is combined with an unproductive, intractable cough. No matter, however, which of the numerous phases this common affection may assume at the onset, certain crucial tests should not be overlooked. I refer particularly to the systematic and persistent use of the clinical thermometer, the tuberculin test and the use of the Roentgen rays—one or all. The adoption of this method is urged, because it has been the most satisfactory for the recognition of phthisis at the earliest possible period. Personal experience enables me to speak with confidence concerning the retrospective diagnostic significance of these clinical criteria, either singly or unitedly; and they establish the existence of a well-defined clinical stage, which is quite variable in duration and presents the ordinary therapeutic indications of this disease. The importance of recognizing this stage springs from the necessity of bringing the cases under appropriate treatment before extensive destructive changes occur and efforts at treatment are hopelessly futile.

It is an accepted position that unless the cell-condition is favorable for the growth and development of the bacilli there is manifested an innate tendency to spontaneous limitation and healing. This fact explains why in more than 50 per cent. of the human family the bacilli not only gain entrance into the body but also effect a lodgment, while less than 14 per cent. of the deaths from all causes are ascribable to tuberculosis. It is true that spontaneous healing occurs most commonly in local varieties of tuberculosis—common in children—as of the lymph glands, bones and joints. I shall deal with the treatment of incipient pulmonary tuberculosis only, and desire to emphasize at the outset that medicines are unquestionably of less value than the more natural agencies, hygienic and climatic, that aim at reinforcing nature's efforts at spontaneous recovery. I have a fixed belief that a successful resistance to the invasive forces in this disease can be best accomplished by an appropriate environment including better hygienic living, better far than by the use of any known serums. The physician often finds well-marked evidences of pulmonary disease at his first examination, and under these circumstances it is clearly his duty to select a suitable climate with particular reference not only to the stage of the affection but more especially to the individual. On the other hand, highly suspicious cases, or such as show afternoon fever, or lung-involvement on fluoroscopic examination, or respond positively to the tuberculin test; even though the microscope fails to reveal bacilli, should be treated in a manner similar to typical incipient tuberculosis, or that showing the presence of tubercle bacilli, since it has been found that these cases usually become characterized soon or late if allowed to drag on without appropriate management. The profession will not awaken to the proper sense of its responsibility until this course is adopted.

The principal object of treatment in all cases is to improve the general nutritive processes, since it is in this way, and in this way only, that the natural defensive processes can gain the day. In general terms, the climatic requisites for consumptives are purity and equability of climate with an abundance of sunshine; dryness of the air and high altitude are of subsidiary value. Delafield's dictum, that that climate "is most suitable in which the patient feels well, eats well and gains in flesh and strength," is excellent. According to my experience, the Adirondack region meets the indications in incipient cases better than any other convenient resort, although I have seen excellent results also from a stay at Thomasville, Ga., Southern California, New Mexico and Colorado. Dr. P. Marvel informs me that Atlantic City gives good results in the more chronic forms of fibroid phthisis. I have found that this popular resort affords excellent advantages during the cold season for incipient cases. The stay should not, in this class of cases, exceed one month or six weeks, and then a change to the mountain resorts already mentioned should be made. Finally, I have witnessed excellent results from a sojourn in the Pocono Mountain region, Pennsylvania. In short, it will be found that an inland locality that affords a pure atmosphere and can boast of the absence of great variations of temperature will produce good results. In this connection I would emphasize the familiar fact that mountain air and that of the virgin forest are helpful, principally because they possess these prime climatic requisites. Forests, particularly pine-groves, favor atmospheric purification, since they generate ozone, which oxidizes the impurities contained in the air; they also favor to an equal extent an equable temperature by maintaining a constant humidity.[28]

As elsewhere stated, while it is essential to send patients to suitable resorts, the most satisfactory results are obtained from the combined climatic and sanatorium treatment. If situated in a suitable climate, and if properly officered and well equipped, they show results that surpass all other known methods of treatment. The principal advantages offered are due to rigid system of hygiene under the close supervision of competent medical officers. As pointed out in a recent paper,[29] there are a large group of cases of incipient pulmonary tuberculosis among the middle and lower classes that require institutional treatment. For such, sanatoria conveniently located in close proximity to large municipalities, though with special reference to such factors as purity of atmosphere and protection from chilly blasts, by natural elevations or the woodland, should be selected. It is scarcely possible to obtain for them the most salutary climate.

[illegible] must bestow close attention on the [illegible] on the condition of the gastrointestinal tract. A preliminary course of gastric antiseptics and stomachics, coupled with an open-air existence little short of injurious exposure, sometimes stimulates the appetite, which is usually poor or even lost, and increases digestive power. The appetite may be rendered keen by a change of air, especially to the seaside, but the patient should not be sent to the seaside during the warm season, if cough be present. I would strongly advise in favor of a rigid system of feeding, even in the early stages, and the French method of forced feeding deserves a trial if there be absolute loathing of food.

Medicinal agents in the early stages are employed to increase the bodily resistance by improving the principal nutritive functions. I would place creosote in this category; it enjoys the confidence of the profession to a greater degree than any other remedy and its use is sometimes followed by lessened cough and expectoration, amelioration of the night sweats, lessened fever, with a gain of strength and weight. Doses no larger than can be tolerated by the stomach are to be prescribed. Indeed, any remedy that interferes in the slightest degree with the function of the stomach is to be withdrawn immediately. Among the most promising remedies employed with a view to improving the nutritive processes is cod-liver oil, when this agent does not tend to impair the appetite and digestion, but on the other hand is well borne. The hypophosphites are especially serviceable in a large proportion of early cases, and the same is true of arsenic, though, perhaps, in a smaller percentage of instances.

THE RELATIVE IMPORTANCE OF VALVULAR AND MUSCULAR LESIONS IN DISEASES OF THE HEART.[*]

SOLOMON SOLIS-COHEN, M.D.
Professor of Clinical Medicine and Therapeutics in the Philadelphia Polyclinic; Clinical Lecturer on Medicine in Jefferson Medical College; Physician to the Philadelphia and Rush Hospitals; Consulting Physician to the Jewish Hospital, etc.
PHILADELPHIA.

It would be incorrect to say that the importance of affections of the myocardium has been but recently recognized; yet it is probably true that the attention of teachers and authors has been much more actively given to these affections during the last four or five years, and that among physicians not engaged in teaching or writing, the subject, while not ignored, has not even yet received the attention it deserves.

One reason for this is that until recently, at least, in the didactic lectures, in the clinical lectures, in the ward classes, and in the quiz room, so much stress has been laid on the diagnosis of valvular lesions and the recognition of cardiac murmurs that the average student leaves college with the conception of valvular murmurs and heart disease as synonymous. In post-graduate teaching I have frequently had experienced men, as well as recent graduates, report that a patient's heart was normal because they had failed to find any valvular murmur. Furthermore, in considering the treatment of patients presenting valvular murmurs, what has seemed to have most weight with the majority of physicians, as observed in post-graduate teaching or in consultation practice, has been the name of the valvular condition—mitral regurgitation, aortic regurgitation, mitral stenosis—while comparatively little attention has been paid to the condition of the cardiac musculature or to the blood-vessels. Concerning the great importance of the vascular system in diagnosis, prognosis and treatment, I have frequently written, and in this communication shall merely allude to the matter. Attention is now directed to the importance of the condition of the musculature of the heart, which experience shows, even if *a priori* considerations did not so indicate, means more for the patient's life and comfort than does the condition of the cardiac valves. To this statement there is but one important exception, namely, the case of mitral stenosis with great narrowing; of which more hereafter.

VALVULAR LESIONS.

In many cases of valvular lesions, even of long standing, compensation is so good that under all ordinary conditions of life the function of the heart is performed almost perfectly; and it is only when extraordinary exertion, mental or physical, or extraordinary emotional strain throws an additional burden on the circulation or calls for more quick adjustment of circulatory relations, that the impairment is seriously felt. To drug such a patient because auscultation reveals an organic murmur at base or apex would be to increase his difficulties, not to lessen them. Treatment by regulation of diet and of physical and mental activities may often be judicious and tend to prolong the period of maintained compensation. For many years I used to show to my ward-classes a man past three score and ten, who had a clear history of mitral incompetence for more than thirty years, and who needed no medicine. I have watched a number of children, whose heart-valves were damaged by endocarditis of scarlet fever, grow into adolescence and manhood, even into womanhood with its duties of maternity, and still need no drugging. Sometimes the hypertrophy exceeds the needs of circulatory compensation, in which case temporary diminution of the patient's activity, purging and the judicious use of bromids and aconite will usually subserve the therapeutic indications. But whether or not the treatment outlined suffices, the point to which attention needs to be chiefly directed is distinctly the muscular condition and action, not the valve-lesion. On the other hand, when compensation has not been good, or having been good has begun to fail, the valvular lesion is, in most cases, but a secondary element in prognosis and treatment. As in all engineering problems, all the conditions need to be studied, and the measures appropriate in mitral regurgitation are often ill adapted for aortic stenosis. But it is pre-eminently the failing muscle that needs to be nourished, strengthened, stimulated or regulated. It is the failing muscle from which the burden needs to be lifted by reduction of physical, mental and emotional activities and by therapeutic devices. Unconsciously, however, the therapeutic lesson has become somewhat organized in the automatic motor apparatus of the profession, and physicians who follow the rules laid down in the text-books or by their teachers for the treatment of various valvular lesions, usually adopt measures which are, in the main, directed toward the indications furnished by those signs and symptoms consequent upon the good or bad condition of the cardiac muscle.

---

[*] Presented to the Section on Practice of Medicine, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

MITRAL NARROWING.

I shall, therefore, not dwell on this phase of the subject, save to direct attention toward the problem presented by cases of mitral narrowing. That this lesion is more common than the older text-books would indicate seems to be becoming the general opinion. Compensation is never fully established, for the obstacle is so placed that neither increased force of cardiac contraction nor increase in the containing capacity of the chamber behind the obstruction can succeed in forcing the due quantity of blood into the left ventricle and thence into the arteries with each systole. Perhaps nothing in cardiac semeiology is more significant than the disproportion between the great systolic energy and the weakness and smallness of the radial pulse, in cases of marked mitral obstruction. In order to permit the muscle to act as effectively as possible under the circumstances, it is necessary not only to dilate the peripheral vessels by nitroglycerin or baths or appropriate exercises, but also to diminish its own wasted and wasting exertions. For this purpose strontium bromid, and even small doses of aconite, carefully watched and regulated, have proved useful; and the apparently paradoxical, but really useful, combination of aconite and digitalis has also been of great service.

HEART DISEASE WITHOUT MURMURS.

It is, however, not in valvular lesions, but in those cases in which rational symptoms of cardiac impairment exist, without murmurs or with inconstant murmurs, that the diagnostic problem becomes most difficult and that routine treatment not only fails to do good but frequently does harm.

ACUTE DILATATION.

I can remember with what diffidence I first made the diagnosis of acute dilatation of the heart, and with how much relief I welcomed the confirmation of this diagnosis by my distinguished teacher called in consultation. Yet acute dilatation, not necessarily fatal, has seemed by later experience not common, it is true, and yet not so rare as to call for the report of isolated cases. In certain subjects it occurs more readily than in others, and the attack may be repeated more than once. I do not refer now to the cardiomyopathies of acute infectious fevers, but to the idiopathic acute dilatation, that is to say, dilatation occurring suddenly or in a comparatively short evolution, from direct strain on the heart.

The readiness with which changes in the size of cardiac chambers may occur is not generally recognized. I recall the case of a boy of 12 years in my dispensary service at the Philadelphia Polyclinic, whom, however, I saw only once, in whose case slight changes of position altered not only the position of the apex but also the transverse area of dulness, as demonstrated by the independent observation of two component diagnosticians. The phenomena of cardiac changes in the warm bath have been made familiar by the publication and multiplication of the observations of the Nauheim school. Fright, and sometimes less severe emotion, especially in the anemic and poorly nourished, will cause acute dilatation of the heart; and this condition may often persist for some time after the cause of disturbance has been removed.

Other causes leading to acute dilatation are the effect of rarefied air at altitudes and sudden, violent, or relatively excessive exertion, as in climbing, bicycling, swimming, or in athletic contests; the general or temporary physical condition of the subject and the physical and psychic environment having much to do in the determination of a relative excess; while the quantitative effort of the skeletal muscles may be less important than its character in determining heart strain. When pericardial adhesions or valvular disease, or innutrition or even latent disease of the myocardium exists, acute dilatation is much more likely to occur.

ACUTE MYOCARDITIS.

Acute myocarditis is common in all the infectious fevers even when endocarditis and pericarditis do not occur. Perhaps rheumatism, diphtheria, typhoid fever, pneumonia and influenza give the most striking examples of this class of cardiac affections, and most physicians recognize this during the persistence of the exciting disease. It is often overlooked, however, after convalescence has begun; and many patients recovering from influenza in particular are allowed to return to active work long before the condition of the heart warrants it. A condition of myopathy is thus set up, and one frequently meets with cases presenting such symptoms of impaired circulation as dyspnea, vertigo, inability to walk rapidly or to climb, sometimes with edema of the extremities, intermittence of the pulse, and precordial distress, in which the origin of the symptoms can apparently be traced to a recent or remote attack of influenza.

CHRONIC MYOPATHIES.

Still more difficult of recognition and more frequently overlooked are the chronic myopathies which have not had distinct origin in some frank infection and which have not followed valvular disease or nephritis.

Recent works upon pathology describe many varieties of myocardial lesion, with various forms of degeneration in the muscular fibers and with varying quantities and distribution of interstitial or substitutional fibrous tissue. Huchard, among the French observers, has made a number of refinements in the nomenclature of these conditions and has described special symptoms observed during life as associated with special forms of myocardial degeneration and interstitial alteration discovered post-mortem. Much of this, however, seems to be premature. It is well that histological studies of the dead heart should be made as systematically as possible, and the utmost information concerning the character of the structural changes gathered: but it is only after a large number of cases shall have been carefully traced in their clinical histories over several years, and the intimate nature of the lesions found after death in such cases carefully collated and compared, that we shall be enabled to analyze the data and establish the signs and symptoms which, observed during life, shall warrant a diagnosis of some special affection of the myocardium. Even the term "myocarditis" as a generic designation seems to be going too far, unless we are prepared to assert that every alteration of the cardiac muscle and every form of increase of connective tissue indicates an inflammation. The French observer's term, gory; it enjoys the confidence of the profession to a greater degree than any other remedy and its use is sometimes followed by lessened cough and expectoration, amelioration of the night sweats, lessened fever, with a gain of strength and weight. Doses no larger than can be tolerated by the stomach are to be prescribed. Indeed, any remedy that interferes in the slightest degree with the function of the stomach is to be withdrawn immediately. Among the most-promising remedies employed with a view to improving the nutritive processes is cod-liver oil, when this agent does not tend to impair the appetite and digestion, but on the other hand is well borne. T[illegible] are especially serviceable in a large [illegible] cases, and the same is true of arsenic, though, perhaps, in a smaller percentage of instances.

---

* Presented to the Section on Practice of Medicine, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

MITRAL NARROWING.

I shall, therefore, not dwell on this phase of the subject, save to direct attention toward the problem presented by cases of mitral narrowing. That this lesion is more common than the older text-books would indicate seems to be becoming the general opinion. Compensation is never fully established, for the obstacle is so placed that neither increased force of cardiac contraction nor increase in the containing capacity of the chamber behind the obstruction can succeed in forcing the due quantity of blood into the left ventricle and thence into the arteries with each systole. Perhaps nothing in cardiac semeiology is more significant than the disproportion between the great systolic energy and the weakness and smallness of the radial pulse, in cases of marked mitral obstruction. In order to permit the muscle to act as effectively as possible under the circumstances, it is necessary not only to dilate the peripheral vessels by nitroglycerin or baths or appropriate exercises, but also to diminish its own wasted and wasting exertions. For this purpose strontium bromid, and even small doses of aconite, carefully watched and regulated, have proved useful; and the apparently paradoxical, but really useful, combination of aconite and digitalis has also been of great service.

HEART DISEASE WITHOUT MURMURS.

It is, however, not in valvular lesions, but in those cases in which rational symptoms of cardiac impairment exist, without murmurs or with inconstant murmurs, that the diagnostic problem becomes most difficult and that routine treatment not only fails to do good but frequently does harm.

ACUTE DILATATION.

I can remember with what diffidence I first made the diagnosis of acute dilatation of the heart, and with how much relief I welcomed the confirmation of this diagnosis by my distinguished teacher called in consultation. Yet acute dilatation, not necessarily fatal, has seemed by later experience not common, it is true, and yet not so rare as to call for the report of isolated cases. In certain subjects it occurs more readily than in others, and the attack may be repeated more than once. I do not refer now to the cardiomyopathies of acute infectious fevers, but to the idiopathic acute dilatation, that is to say, dilatation occurring suddenly or in a comparatively short evolution, from direct strain on the heart.

The readiness with which changes in the size of cardiac chambers may occur is not generally recognized. I recall the case of a boy of 12 years in my dispensary service at the Philadelphia Polyclinic, whom, however, I saw only once, in whose case slight changes of position altered not only the position of the apex but also the transverse area of dulness, as demonstrated by the independent observation of two component diagnosticians. The phenomena of cardiac changes in the warm bath have been made familiar by the publication and multiplication of the observations of the Nauheim school. Fright, and sometimes less severe emotion, especially in the anemic and poorly nourished, will cause acute dilatation of the heart; and this condition may often persist for some time after the cause of disturbance has been removed.

Other causes leading to acute dilatation are the effect of rarefied air at altitudes and sudden, violent, or relatively excessive exertion, as in climbing, bicycling, swimming, or in athletic contests; the general or temporary physical condition of the subject and the physical and psychic environment having much to do in the determination of a relative excess; while the quantitative effort of the skeletal muscles may be less important than its character in determining heart strain. When pericardial adhesions or valvular disease, or innutrition or even latent disease of the myocardium exists, acute dilatation is much more likely to occur.

ACUTE MYOCARDITIS.

Acute myocarditis is common in all the infectious fevers even when endocarditis and pericarditis do not occur. Perhaps rheumatism, diphtheria, typhoid fever, pneumonia and influenza give the most striking examples of this class of cardiac affections, and most physicians recognize this during the persistence of the exciting disease. It is often overlooked, however, after convalescence has begun; and many patients recovering from influenza in particular are allowed to return to active work long before the condition of the heart warrants it. A condition of myopathy is thus set up, and one frequently meets with cases presenting such symptoms of impaired circulation as dyspnea, vertigo, inability to walk rapidly or to climb, sometimes with edema of the extremities, intermittence of the pulse, and precordial distress, in which the origin of the symptoms can apparently be traced to a recent or remote attack of influenza.

CHRONIC MYOPATHIES.

Still more difficult of recognition and more frequently overlooked are the chronic myopathies which have not had distinct origin in some frank infection and which have not followed valvular disease or nephritis.

Recent works upon pathology describe many varieties of myocardial lesion, with various forms of degeneration in the muscular fibers and with varying quantities and distribution of interstitial or substitutional fibrous tissue. Huchard, among the French observers, has made a number of refinements in the nomenclature of these conditions and has described special symptoms observed during life as associated with special forms of myocardial degeneration and interstitial alteration discovered post-mortem. Much of this, however, seems to be premature. It is well that histological studies of the dead heart should be made as systematically as possible, and the utmost information concerning the character of the structural changes gathered; but it is only after a large number of cases shall have been carefully traced in their clinical histories over several years, and the intimate nature of the lesions found after death in such cases carefully collated and compared, that we shall be enabled to analyze the data and establish the signs and symptoms which, observed during life, shall warrant a diagnosis of some special affection of the myocardium. Even the term "myocarditis" as a generic designation seems to be going too far, unless we are prepared to assert that every alteration of the cardiac muscle and every form of increase of connective tissue indicates an inflammation. The French observer's term, "myopathy," or, if we prefer to Anglicize it, "muscle disease," is better, and represents the full extent of present accurate knowledge applicable during life, to the diagnosis of the vast majority of the chronic cases which have not followed acute infectious diseases.

CAUSATION.

Among the principal causes of disease of the cardiac muscle in American men is the long-continued, even moderate, use of alcohol, and especially when this has been associated with the use of tobacco. I have not observed the same degree of impairment in those who have used alcohol alone or those who have used tobacco alone as in those, and these, of course, form the majority, who have used both. What constitutes temperate use of alcohol or tobacco varies very much with the individual. In some patients disturbance of the cardiac rhythm and irritable and weak over-action of the heart begin soon after the smoking habit has been established. In others it occurs only toward the involution period of the organism; that is, after middle life. It is probable that the changes induced by tobacco are but slight at first, so slight that we are warranted in considering them neuro-functional; but that the long and constant repetition of these disturbances finally, by exhaustion of certain qualities in the cardiac cells, brings about degenerative structural change. The same may be true of alcohol, though the well-known tendency of this drug to produce sclerotic changes in general warrants the belief that in the alcoholic myopathies structural changes are present from the first. Alcohol and tobacco usually give rise to other sclerotic changes also, in the vessels especially, which secondarily lead to impairment of cardiac nutrition by ischemia and to increase of the work placed on the heart to carry on the circulation, owing to the heightening of peripheral resistance. Thus, further changes occur in the cardiac muscle in addition to the direct effect on it of the poisons, and to exhaustion through their influence on the nerves. Gout or lithemia, grouping under this head those general conditions of toxemia associated with the overproduction of uric acid, but in which xanthin and hypoxanthin and other alloxuric products may be equally potent, is often, too, associated with the alcoholic habit; but in cases in which alcohol is used not at all or but moderately, and in which there exist hereditary tendencies to this perversion of metabolism, myopathy is not infrequent. So, too, syphilis, in association with or independent of alcohol, may give rise to changes in the heart, not necessarily gummatous, which in turn give rise to vague clinical symptoms often difficult of interpretation. Sexual excesses, mental strain, especially if worrisome, physical overwork, whether in the serious pursuits of life or in games and athletic exercises, malnutrition, lead poisoning, the abuse of tea and coffee, and, in exceptional cases, emotion, are to be added to the list of causes.

RATIONAL SYMPTOMS.

The symptoms, at first, at least, are usually vague. They are inconstant, not only as regards different cases, but as regards the same case at different times. At first, and sometimes throughout, they may be comprised under the general head of rational rather than physical signs. Death, indeed, may occur suddenly without any known history of either rational or physical signs. It is probable that in most cases, if not all, with the exception of cases of fatty infiltration and fatty degeneration, the earliest stage is one of hypertrophy—a pathologic, not a physiologic or compensatory, hypertrophy—this being followed by exhaustion of the undifferentiated cellular elements out of which new fibers are furnished for growth and repair, and this, in consequence, by degeneration of muscle tissue and proliferation of connective tissue. Overaction, spasmodic and irritable in character, is, therefore, followed by defective and irregular action, and the progress of lesions is marked by a corresponding change in the associated semeiology. Dyspnea, constant or occurring especially on slight exertion, tinnitus aurium, headache, dilatation of the pupil, vertigo, vague sensations of cerebral and precordial distress, sometimes actual pain, not rarely angina pectoris, cervical and occipital pain, slight blueness of the lips, injection and later dulness of the conjunctiva, increased force and tension, later irregularity and intermittence of the pulse, sometimes transient edema, often digestive disturbance, unaccountable languor, drowsiness, undue readiness to fatigue, irritability of temper, sudden cardiac palpitation and occasional and increasing periods of very slow and feeble action of the heart are noted, but not all at the same time or in the same patient. Besides this, it is evident that many of these symptoms are common to a variety of affections. Many of them may result from indigestion, most may occur from anemia, many are associated with nephritis, and they are nearly all to be found in neurasthenia. Especially difficult is it at times to differentiate between the unbalanced action of the neurasthenic heart and the irritability of impaired power of the myopathic heart. One needs to be specially guarded in such a diagnosis, for the statement to a neurasthenic that he has heart disease may so frighten him as to produce it. Murmurs are perhaps more common in neurasthenia than in pure myopathies, the arrhythmia is more changeable in its type, and the general characteristics of the patient are to be taken into consideration. In gouty neurasthenics and in other gouty subjects it is easy to refer to the heart the pain of intercostal neuralgia, and in both gouty and syphilitic subjects it is easy to mistake the pain of costal periostitis for cardiac pain. Sometimes, however, genuine cardiac pain of myopathy or vascular sclerosis, intercostal neuritis and gouty or syphilitic periostitis are all present. Mistakes are only to be avoided by careful observation and weighing all the phenomena of the case.

THE COSTAL FRINGE.

Verging on the definition of physical signs, and I believe quite significant of cardiovascular alteration, are ectases of superficial veins, most marked on the face and thorax; in the latter situation sometimes forming what I have denominated the costal fringe, that is to say, a network of very fine red, pink or blue vessels following the borders of the costal arch like a fringe of embroidery. This, however, is sometimes found in patients presenting no rational or physical symptom of cardiac disease, and is not infallible. Usually the cardiopathic patients who present it show slight permanent enlargement of the liver, and are subject to attacks of engorgement of that viscus.

PHYSICAL SIGNS.

As regards percussion and auscultation, these are, in the late stages of myopathies, quite definite, but not so in the earlier stages. An increase in the precordial dulness in both directions laterally, with displacement of the apex-beat downward and to the left, gradually takes place. Sometimes the increase is irregular in outline, and one suspects localized dilatation of the heart, or cardiac aneurysm. With this at last goes feebleness, perhaps disappearance of apex impact or weakness and diffusion of the wave. An impurity rather than a definite murmur of the systolic sound is among the early signs, as is also, and I think this is quite significant, an approximation in quality between the first and second sounds. The first sound is shortened in duration and its tone becomes more valvular. Sometimes the second sound is relatively or actually accentuated. Later the sounds become rather empty, resembling in rhythm and in character the muffled drum of the fetal heart. This embryocardia is easily recognized, and is significant in diagnosis. Duplication of the first or second sound may be developed. Gallop rhythm is never an early sign, but its evidence of muscle-weakness is always clear, whether in uncomplicated myopathy or in failure of compensation in cases of valvular lesion. Intermittence, even to asystole, is also significant, yet one may watch and wait for three or four minutes before he notes the dropping of a single beat, either with the finger at the wrist or with the ear over the apex, and then several beats may be dropped in a minute, sometimes as many as one beat in every four or five. Sometimes the patient himself has a sensation of stoppage of the heart, and this may or may not be accompanied with an actual intermission. It may take place frequently or but rarely. In one of my cases it was said to occur but once a day. With the patient quiet, whether recumbent or seated, or even standing, there may be neither intermittence nor irregularity; yet slight exertion, or even change of position, induce both. Among the symptoms on which I am acustomed to lay stress in the diagnosis of myopathy is undue readiness to change in the frequency or character of the pulse on slight change in the position, activity, or emotion of the patient. The volume, tension and strength of the pulse vary greatly in different cases or in the same case from day to day, and are, of course, affected by the presence or absence of concomitant disease of the arteries, the latter being usually present. They vary much, also, under medication, more, perhaps, than in uncomplicated valvular disease. Murmurs are sometimes present, constantly or inconstantly, due not so much to sclerotic changes in the valves—although these doubtless occur at times in connection with the sclerotic changes in the parenchyma of the heart—as to relative insufficiency.

For complete closure of the cardiac orifices the valves alone do not suffice. The musculature, not only of the auricular and ventricular walls, but also the papillary muscles, must act perfectly, in order to secure complete occlusion of an orifice in systole. Failure to accomplish this gives rise to adventitious sounds. Sometimes these are so marked that the incorrect diagnosis of valvular lesion is difficult to avoid.

TREATMENT.

In the treatment of these conditions, endeavor should be made to remove or mitigate the exciting causes which are usually in continuous influence. In the cases of coffee, tea, alcohol and tobacco this is extremely difficult, sometimes impossible. The reduction of the mental and physical activities of the patient is usually desirable, though this should not be pushed to excess in early cases, in the absence of such symptoms as edema, or evidence of pulmonary or visceral congestion, because the nervous worry induced may be so harmful as to overbalance the gain. It is always well, however, unless there is some counterindication, to reduce the work placed on the heart by the use of nitroglycerin in small doses; sometimes so little as 1/400 of a grain twice a day answers the purpose. The diet is, of course, to be carefully regulated, the skin and the eliminative functions generally are to be kept in good condition, and all excesses are to be avoided. All this "goes without saying." Warm carbonated, saline baths, with massage and gently resisted movements, after the method of Schott, of Nauheim, but modified to suit the individual patient, have been of great benefit in many of my cases—so much so that the patients have often wished to continue the treatment when I have thought it best to intermit. These measures should never be kept up for too long a period consecutively, though they may be renewed from time to time. The question of exercise in some of these cases is very difficult; for with the gouty and in the early stages of their cardiopathy it is often desirable to prescribe moderate exercise. The tendency of the patient is to do nothing, or to indulge in exercise, as in other things, immoderately and spasmodically. This, therefore, becomes a question of good judgment in the individual case, not only as to the requirements of the case, but as to the trustworthiness of the patient. When severe symptoms are present, absolute rest becomes necessary.

Among drugs to strengthen the heart, improve its nutrition and regulate its action, strychnin is the most generally useful. One may also employ from time to time digitalis, of whose preparations (following Beates) I prefer Merck's German digitalin; adonis, of which a good extract or the glucosid adonidin may be used; spartein sulphate, caffein, cactus, of which last the fluid extract or a solid extract may be used, or strophanthus in the form of tincture or solid extract. Much might be said concerning their choice in different cases, but such is not the main object of this paper, nor does time permit. Whatever drugs are used, none should be used continuously, but judicious alternation should be resorted to, and sometimes combinations will in individual cases act better than single drugs. Arsenic is of service as a general nutrient, as are also iron, gold and sodium chlorid, and sometimes, in syphilitic cases, courses of mercurial inunction. with sweating by means of hot baths, followed by potassium iodid in full doses. In some cases, both of syphilitic and non-syphilitic patients with tobacco heart, potassium iodid in small doses is of service. In gouty cases the strontium salts, both iodid and bromid, have seemed of service, not only as addressed to the underlying condition, but also as soothing the cardiac action. For combination with these, when needed, strontium lactate is an excellent diuretic. In acute conditions of cardiac incompetence, whether in the course of chronic valve and muscle disease or suddenly arising without previous disease, venesection is usually indicated. The heart can not empty itself, the patient is in great danger, and blood should be drawn promptly, fearlessly, and in sufficient quantity to afford relief.

SUMMARY.

1. In the great majority of cases of chronic disease of the heart, the exact site and nature of the valvular lesion, while always to be taken into consideration in treatment, are of less importance therapeutically and prognostically than the state of the cardiac muscles.

2. The most important exception to this general rule is in the case of mitral stenosis with great narrowing. Aconite is often of use in this condition to reduce the excessive muscular effort, even when compensatory hypertrophy has not become sufficient.

3. In many cases in which no evidence of valvular lesion can be detected during life, and in some of which slight valvular alterations, in others normal valves, are

demonstrable after death, there exist rational signs of cardiac incompetence which are due to diseases of the cardiac muscle.

4. The symptoms and physical signs of cardiac myopathy are inconstant, and in the early history of the case may be slight. In the absence of valvular lesions, intermittence or irregularities of the pulse or apex-beat, disturbance of rate or rhythm by slight causes, and recurrent pain referred to the precordium, in non-hys*terical and non-neurasthenic subjects*, are the principal local symptoms calling attention to the disease of the cardiac muscle. Tinnitus, vertigo, dyspnea, venous ectases, visceral congestion, edema, and other evidences of circulatory disturbance may be slight and escape attention until sought for. There is usually impurity or weakness of the first sound of the heart, with approximation of the two sounds in quality or relative accentuation of the second sound; later embryocardia and gallop rhythm may develop.

5. Gout, syphilis, alcohol and tobacco, tea and coffee, sexual excesses, mental strain and physical overwork, *either in serious pursuits or sports, are among the chief* provocations of disease of the myocardium, apart from those lesions *secondary to the acute infections* or consecutive to nephritis or valvular disease. Among the acute *infections, influenza is a frequent cause of cardiac* muscle disease.

6. Other than the general diagnosis of disease of the myocardium, there is not yet sufficient knowledge of clinical signs to permit accurate recognition antemortem of the pathological nature of the lesion.

7. The diagnosis between neurasthenia of the heart and disease of the myocardium may be difficult.

8. The *chief importance of the subject lies in the* avoidance of error; *a,* in the prognosis and treatment of valvular disease which may be overtreated or undertreated through failure to estimate properly the condition of the muscle; *b,* in the recognition of serious lesion of the muscular structure of the heart in cases that have been supposed to be normal because *of the absence of valvular murmurs; c,* in the distinction between organic muscular lesions and functional disturbance, and in the realization of the fact that the latter may lead to the former.

9. In treatment, judicious regulation of diet, rest and exercise; avoidance of exciting causes and excesses of any kind; the good functional condition of the skin and eliminative organs, are of the *first importance.* Warm, saline, carbonated baths and, in some cases, gentle massage and resistance exercises carefuly adapted to the individual case, are of great benefit. Nitroglycerin is the most useful single agent of the materia medica. Strychnin, digitalis, adonis, cactus, strophanthus and spartein have usefulness in individual cases. Arsenic, gold and sodium chlorid and iron are useful tonics. Potassium iodid and mercurials sometimes have special indication. Venesection should be made promptly and sufficiently in the case of sudden and urgent symptoms of cardiac failure.

Amalgamation of Parisian Societies.—Several of the Paris medical, surgical and therapeutic societies are seriously discussing the question of federating, to the extent of allowing the members of one society free access to the meetings of the rest, and publishing a common bulletin of the transactions, otherwise retaining autonomy. Among other arguments in favor of the plan are the increased attendance, stimulated emulation, greater publicity and, above all, the better utilization of the treasures of practical experience too often lost at present.

A CLINICAL STUDY OF MYOCARDITIS.[*]

LOUIS FAUGERES BISHOP, A.M., M.D.
Secretary New York Academy of Medicine; Member Neurological Society, Society Alumni St. Luke's and Sloane Maternity Hospitals; Attending Physician Colored Hospital; Assistant Physician French Hospital, etc.
NEW YORK CITY.

It happens in every one's experience that at particular times clinical observation is specially rich in a single direction. So it has seemed to me that during the past year there have been under observation, both in hospital and *private practice,* a great number of cases in which the heart muscle seemed to be primarily at fault. From the study of these cases I have come to believe that disease of the heart muscle is a greater factor in the condition of *many* patients than is usually believed; particularly have I been more and more impressed with the fact that the importance of valvular and arterial disease depends on the behavior of the heart muscle in connection with these lesions. A recognition of the interpendence of arterial and myocardial disease moreover gives new interest and importance to the early recognition of a tendency to an increase of arterial tension. The *first indication to the patient of* this condition may come through the failure of the heart after having struggled a long time *with high arterial* tension. The same is true of valvular disease. The lower grades of incompetency of the valves *give little* or no discomfort so long as the muscle of the heart is intact. These lesions only give symptoms when *some disturbance of the heart muscle renders them relatively* important.

The lesions of the valves are detected by auscultation. Auscultation also renders valuable aid in detecting the condition of the heart muscle, but the great test is the capacity of the muscle to respond to additional work, and if the choice were given of an examination of the heart by direct or indirect methods, *I believe* the most valuable information would be received by testing the heart's power under varying conditions. A man who can go up stairs rapidly without loss of breath or undue increase in the pulse-rate has certainly a fairly sound heart-muscle. Another man subjected to the same test might show marked signs of distress. *yet these men, when examined quietly in bed, would perhaps* give practically the same myocardial signs.

Myocarditis is eminently a *clinical disease in that* the gross post-mortem findings are not co-ordinate with clinical symptoms. A poor heart doing good work may give far less marked symptoms than a good heart doing poor work, *and yet the hope for the future of the latter is far brighter than the former.* So while there are well-marked cases that *we may study and catalogue* with a fair degree of confidence, there are other cases in which it must be confessed there will *always* be doubt as to the degree of competency of the heart-muscle. A great deal depends on the blood-vessels. A temporary anemia of a damaged heart through the spasmodic contraction of the *coronary arteries may* cause a fatal attack of angina, while had the patient escaped such an accident he might have lived for years in comparative comfort. We have seen in the hospital patients living for months and years with progressive degeneration of the heart, until finally when they died it was a source of wonder how a heart so degenerated could have carried on its work. Perhaps the most acute cases of myocarditis are the syphilitic ones. In some of these, particularly the untreated cases, the disease directly attacks the heart, and we have a true syphilitic inflammation. In others it follows the type of a more chronic form. In either case the indications for active treatment are urgent.

---

[*] Presented to the Section on Practice of Medicine, at the Fifty-first Annual Meeting of the American Medical Association, held at *Atlantic City, N. J., June 5-8, 1900.*

There are two great divisions of myocarditis, which also divide the condition into two very nice clinical groups, diseases of the myocardium, due to the direct influence of infectious disease on the heart muscle, and, second, myocarditis, due to the indirect influence of disease of the blood-vessels or the participation of the muscles in the causes of this disease.

Disease of the blood-vessels acts in two ways in interfering with the integrity of the heart-muscle. It renders the work of the heart more difficult by making it necessary to overcome greater resistance on account of the inelasticity of the vessels, and it also interferes directly with the blood-supply to the muscle itself through disease of the coronary arteries.

The relation of pain to cardiac disease is worthy of study. The interior of the heart is, of course, insensitive to pain, and extensive valvulitis may exist and the patient be entirely unconscious of it. Pericarditis gives pain and tenderness on pressure over the heart. Patients with chronic cardiac disease do suffer from time to time more or less discomfort in the region of the heart, though pain in this region is so common that it is almost an axiom that most pain supposed by patients to be from the heart is of gastric origin. However, connected with chronic cardiac disease is a form of pain of extraordinary severity and terrible significance. Angina pectoris is an agonizing pain in the region of the heart shooting to the shoulders and frequently accompanied by the sense of impending death. All attacks are not so severe. No definite explanation of angina pectoris has ever been offered. True angina is invariably associated, however, with disease of the arteries of the heart and of the heart-muscle. The attacks are sudden in their onset and usually end in recovery. Death during an attack is, however, frequent, though sudden death often occurs in patients subject to angina without the definite development of an attack.

The significance of pain in the left shoulder and breast, when occurring in a severe neuralgic form, is always a topic of interest. Particularly is this so when occurring in persons with no recognized cardiac disease. From observation of such patients it seems to me that such pain is of cardiac origin in a much greater proportion of cases than we realize. Its significance is often hard to make out because these patients go on for months and years without any sensation. Their hearts sometimes act better and sometimes worse, and from time to time they have attacks of pain, but these attacks of pain do not bear any relation to the cardiac action, yet occurring as they do in these subjects we can not but believe that they are of cardiac origin. The lesson to be learned is that when persons past middle life are subject to attacks of severe pain, referring to the left breast and the left shoulder, there is reason to suspect myocardiac disease and institute a careful observation. Cardiac pain has been too definitely classified, for there is no real distinction except in degree between the slighter and the most severe forms. Nor is the pain always confined to one side of the chest. The heart itself is not liable to tenderness. It is an anatomical fact that there is a connection between the nerves of various viscera and the nerves of the corresponding portions of the surface of the body. From this fact it is possible for a disease of a viscus to cause pain and tenderness of the overlying tissues.

The chief symptom of myocarditis is a failure in the power of the heart to respond to demands of extra work, though this is not the symptom that is first developed. The earliest symptom is an irregularity in force and rhythm. The origin of this symptom is probably in the muscle itself in that it does not respond with regularity [illegible] nervous stimuli. There is another [illegible] e and rhythm that undoubtedly has its action in irregularity of the nerves themselves. It is between these two causes of this symptom that the greatest difficulty of diagnosis arises, and there are cases in which one can only be certain of the existence of myocarditis when there is developed a deficiency in the power of the heart-muscle.

There is no element in the diagnosis of a case that is so difficult to define and yet which makes so profound an impression on the diagnostician as the quality of the pulse. The other day I saw a patient suffering from a slight cold and not supposed to be in any way seriously ill, nor could I by careful examination and questioning define any symptoms of serious disease, and yet her pulse, though not quick, was of a character that showed an incapacity of the heart to do its work. Each beat seemed to throw a mass of blood through the artery like a projectile, the tension between the beats apparently being nothing. The woman was large and not at all firm in her mucular tissue, and had suffered from an attack of pain in the left shoulder at one time recently. This made a diagnosis of myocarditis justifiable, though as yet she did not suffer any conscious symptoms of cardiac insufficiency.

Myocarditis is unusually common in colored people, possibly due to syphilitic infection and to the natural tendency of mixed races to degenerative changes. In the world at large this relative inefficiency of the heart-muscle accounts for the lack of energy, the inability to maintain continuous labor and militates most forcibly against the progress of the colored race when modified by white blood.

The following case illustrates the development of myocardial changes in a hypertrophied heart. I received an urgent call to see a woman between the ages of 60 and 70 years, and found on arriving at the house that she had been up all night suffering from marked shortness of breath and a hacking cough. At first glance the case almost suggested pneumonia, but that supposition was dispelled by the first question or two into the history. It seems that the patient had had unusually good health, never being ill in any way up to about four years ago. At that time she underwent great sorrow and worry at the time of the death of a near relative, became nervous and much run down. Since then she has not been strong. Two years ago she broke her arm, and was annoyed by this for a long time. Beginning at an indefinite time, but most marked for a year and a half, she had been short of breath on exertion, and has not felt equal to undertaking anything. During the past few months this shortness of breath has been more marked, and particularly so since a few weeks ago, when she [illegible] in climbing the stairs of the elevated railroad and taking a prolonged and difficult trip to a neighboring borough. For the past three days since she has had a cold, her breathing has been quite short at times and she could not lie down with comfort at night.

I found her lying in bed, suffering from considerable dyspnea, with a decidedly anxious expression.

heart apex was well outside and below the nipple line. Over the apex there was an indefinite systolic murmur, but what was most noticeable was a heaving pulsation of the heart with an accentuation of the aortic sound. Palpation gave the impression of a thick, heaving sac. From the commotion the heart was making it would seem incredible that it was not doing its work, and yet it was evident from a careful consideration of the case that the heart was not only hypertrophied but dilated so that while there was considerable muscular action there was an insufficient contraction of the cavity of the heart to carry the blood properly forward.

The effect of large doses of digitalis on myocarditis that had gone untreated, and which are seen in a late stage is interesting. The foregoing case was given 4 minims of the extract of digitalis every four hours. After taking about six doses the effect on the heart was very marked in that the beats became slower and better separated from each other; the cardiac action, which previously seemed like a peristaltic wave in a thick-walled distended sac, became more like heart beats. The cardiac area markedly diminished. With the digitalis was given iodid of sodium in 5-grain doses. Unfortunately, in the anxiety of this most desperate case the digitalis was carried a little too far, for the patient, while being entirely freed from dyspnea, suffered several attacks of faintness, during which the heart action became extremely slow. This passed over, and later on the patient was nauseated and vomited a small amount of clam broth that had been given. The subjective sensation of nausea continued for some time. During the attack of faintness an overzealous friend administered a tremendous dose of whisky, so that may have had something to do with the nausea. However, it was evident that the patient was suffering the physiologic symptoms of digitalis. This heart was so much dilated and action was so bad that we believed it justifiable to push the drug immediately to this extreme limit. Vomiting in such a case does not do any particular harm, and indeed there are theoretic advantages. Vomiting certainly does clear up pulmonary congestion, and it would seem probable that the violent contractions of the diaphragm and chest with the nervous stimulation might give the opportunity for a dilated heart to gather itself together. At any rate, in spite of the disturbance of the digitalis, the patient's heart action was infinitely improved. A gentian mixture containing the iodid of sodium was substituted for the digitalis, and 1/60 grain of strychnin and 1/100 grain of nitroglycerin given on alternating hours. One can not insist too strongly on the importance of complete physical rest in such cases.

Since beginning this paper I have had the opportunity of making a pathologic examination of a case that is so typical of a certain class, and which together with another case forms a picture of syphilitic myocarditis that was most interesting. Two patients were admitted to the hospital three or four days ago; the one a woman complaining of pains in the bones, worse at night, and presenting ulcerations and old scars in the upper tibial region. The scars were pigmented, and the ulcerations were punched out in appearance. There was no difficulty or hesitation in the diagnosis of syphilis, and as no case of syphilis had been presented recently, it was made the occasion for a brief description of this disease. While speaking the house physician informed me that after the clinic there would be an autopsy on a case that I had seen two days before. I went on to describe this case as being typical of fatal visceral syphilis in a comparatively young person. It was a man who came to the hospital without a very clear history except that he had gradually failed in strength. He was well nourished, and had not the appearance of a very sick man as he lay quietly in bed, but an examination of the heart showed that the muscular sounds were feeble and greatly irregular in force and rhythm. The area of cardiac dulness was somewhat increased toward the left. He showed the same scars over the tibiæ. At the autopsy were found in the heart areas of fatty infiltration, patches of whitish thickening and a pallor of the pericardium. The heart-muscle was flabby and there was a moderate degree of atheroma of the vessels. The other organs were fairly healthy, except that there was a moderate amount of fluid in the right pleural cavity. The man had died suddenly without warning, apparently from a failure of the action of the much diseased heart-muscle. This with the case of syphilis made a very striking and terrible picture and illustrated forcibly that type of myocarditis that occurs in comparatively young people from syphilis. It has been well taught that syphilis resembles in type the other infectious diseases, and, though covering a long course, can be compared at all points with the acuter diseases of this class.

The following case, seen in consultation, is a good illustration of myocarditis of a certain type. A man, 39 years of age, gave a history of having for a number of years had attacks of pain in the side, very severe but not very definite in location or constant in character. These attacks came unexpectedly, and between the attacks he felt perfectly well. The pain was not attributed to cardiac disease. However, for about two years he has complained of discomfort in the region of the heart, and at times of dyspnea on exertion. Still, he was not very sick, and kept on with his work as a builder. Two months ago the dyspnea gradually became much worse, so that he could not lie down, and he came under medical treatment. This dyspnea has never been entirely absent since, and he has developed a good deal of edema of the lower extremities. Physical examination shows a man of not unhealthy appearance, and fairly well nourished, but suffering from extreme shortness of breath, which is exaggerated by the slightest exertion. The heart apex is diffused, but is distinctly felt about two inches to the left and an inch below the nipple. The heart's action is rapid and fairly regular, the first sound being indistinct. In the region of the nipple, and also toward the axillary line, there is a short systolic murmur. The sounds at the base are indistinct, and no murmurs referable to the aortic valves can be made out. The pulse is rapid and feeble, the artery being badly filled. The left lung shows feeble breathing toward the base, which condition is more marked in the right, where some coarse râles are heard. The liver is markedly enlarged and tender, though there is apparently no fluid in the abdominal cavity. The legs and thighs are edematous, but there is no edema of the skin of the upper parts of the body. The urine is said to be fair in amount, contains a considerable quantity of albumin, but no casts. So we have a man 39 years old developing all the signs and symptoms of a heart that is enormously dilated, and which has lost the power of carrying on the circulation. An unusual feature of this particular case is that the heart's action, though having progressed so far toward complete failure, still remains fairly regular. The origin of myocarditis in this case is entirely obscure. The man's parents are living and well, so heredity can be excluded. There is no history of specific disease or rheumatism and no abuse of alcohol. The man has worked hard, but apparently not in a way to impair his health. It is probable that there have ben slight arterial changes, which have affected the coronary arteries out of proportion with the general arterial system.

Myocarditis is a penalty that comes to those who are intemperate, whereby the tissues of the body are either poisoned by alcohol or allowed to degenerate from disuse. It comes also to many who are intemperate in work and worry, whereby the heart is, as it were, worn out, and it comes last of all as a complication of inflammation of the endocardium or pericardium as a direct true inflammation. The exaggeration of the importance of valvular disease is only natural when it is considered that the symptoms are so plain that they are among the earliest that come to the attention of the physician and among the most striking that he ever encounters, while on the other hand the condition of the heart-muscle presents many difficulties in diagnosis and prognosis. Still, to the patient student of disease. the heart-muscle will ever afford a fertile field for thought and observation.

A PLEA FOR A MORE RATIONAL PROGNOSIS IN CARDIAC AFFECTIONS.*

J. J. MORRISSEY, A.M., M.D.

Visiting Physician St. Joseph's Hospital; Chief of Clinic Outdoor Department St. Vincent's.
NEW YORK CITY.

The prognosis of many of the cardiac affections, both of the orifices and of the walls, is frequently given an exaggerated importance not commensurate with the real conditions present. The Father of Medicine has said: The art of physic is of great extent; life short, opportunity slippery, experience fallacious, and judgment difficult. The universal applicability of this dictum is acknowledged, but it is more truthfully applied to diseases of the heart than to any other of the many ills to which flesh is heir. There are so many factors to be considered in arriving at a definite prognosis, that the possession of excellent judgment, the use of accurate observation, and the power to survey the whole situation in a masterly manner, should be concentrated in every case of heart disease. In striving to render an accurate prognosis in this particular sphere of disease manifestation we should establish first, a true estimate of the nature and extent of the changes which have occurred; in other words, the development of the point to which we have briefly alluded. namely, a complete diagnosis. This should be based, not so much upon the physical signs, which are frequently deceptive and limited in character, but on a consideration of organs far removed from the thoracic cavity, whose relations while not intimate, yet are closely affiliated with the results arising from an interference with the circulatory system in consequence of the cardiac disease. Our thoughts should never be centralized on the heart itself to the exclusion of other considerations, which, even more than any conclusions derived from physical signs, may be of paramount importance in aiding us to arrive at a definite prognosis.

In the second place, we should obtain an accurate and comprehensive history as to the causation of the affection, whether produced by a recurrent or non-recurrent disease, the length of time it has persisted, whether it was recognized subjectively, or became known to the patient during a cursory examination, in the line, for example, of life insurance, points which will bear further elucidation.

In the third place, make a close consideration of any special features characterizing the case in question. This last statement must always appeal to the careful diagnostician, for in the whole range of human maladies, there is probably no class in which the undefined personal equation is of so much importance, as in an accurate estimation of the prognosis of heart disease. Given two patients with, for example, a lesion of the mitral valve with exactly similar signs, and alike as to occupation and environment, and the course of the affection may be entirely different. In one the progress may be inevitably downward, despite the administration of remedies of known efficacy, while in the other, the structural integrity of the cardiac tissue may be preserved far beyond our expectations by appropriate treatment. It is stated, and with truth, that physical signs in heart disease can not, at all times, be relied on as evidence of the nature and extent of existing morbid changes and their tendencies. A too narrow reliance must not be placed on the indications afforded by close physical examination. The stethoscope will discover the "physical sign proper," the murmurs, and enable us to place them in the various classes of valvular defect from which they originate. But here its function ends; it does not inform us what is in reserve for this particular patient. Again, it is fully recognized that the quality of the murmur is no guide to the amount of valvular mischief present. The loudest murmurs frequently accompany inconsequential lesions. while at other times, the effects of a valvular defect may be too grave for the production of any murmur. A loud murmur is generally of less serious import than one which is weak and soft; for the former is indicative of force in the heart's action, while weakness of the heart constitutes the greatest of all dangers. Yet it must not be deduced that a soft or weak murmur necessarily signifies either a failing heart or a greatly damaged valve; still a diminution of the intensity of a murmur, gradual or sudden, may confirm unfavorable indications afforded by symptoms. A long murmur, except in a case of mitral or aortic stenosis, is usually an indication of early and comparatively slight disease and of efficient cardiac action, while a short murmur may be and generally is significant of impending danger. An accent at the beginning of a murmur shows that the valves still act as a check on the reflux of blood.

Each case then must be judged on its own individual merits, and this brings us back to our former contention, namely, that the intrinsic value of organs of similar structure varies in different individuals. Intrinsic strength and vitality are not simple qualities but are complex in character—so complex indeed that their consideration means the investigation not alone of the patient himself, but of his progenitors, the diseases of which they died, their power to overcome certain maladies, and to quickly succumb to others, the whole question of heredity, a topic of such immense ramifications as to be practically forbidden even in part, in a paper of the limited scope which I have the honor of presenting. Let me add in connection with this subject, that we are accustomed to note a hereditary tendency to the decay of certain external structures, such as the hair and teeth; is it not plausibl to suppose that the internal and more vital o g.

---

* Presented to the Section on Practice of Medicine, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

follow the same course. Decay is hereditary as to cause, as to structure affected, and also, as to time. These are affected by the interaction of the constitution of parents whereby is produced either an accentuation of the tendencies in certain directions, with a diminution of vital powers in the offspring, or an increase of the vital powers, and the production of a corresponding force to maintain the system against the encroachment of disease, or when once disease has invaded the citadel of health, to fortify it against further advancement. A broad and comprehensive view then of all the factors, both recent and remote, both of health and disease, both of an acquired and hereditary character, must be taken before we can build a stable foundation on which the elements of a correct prognosis can be established. This is the only way in which the true gravity of a lesion can be measured, and we should always strive to determine, first, what has been its effect on the heart itself, then how far beyond its influence has extended. If it is found that a murmur is present, no matter at what orifice, and there is no change in that portion of the heart on which the strain is first exercised, and if it is also known that the murmur has existed a sufficient length of time for the effects of increased work to have been manifested, then it follows that the affection is stationary, and may remain so for an indefinite time. On the other hand, if hypertrophy or dilatation, or both exist, their degree is a test of the actual interference with the heart in its work. Due weight is also given to the condition of the pulse, the presence of dyspnea, or palpitation, or syncope, and to any evidence of interference with the pulmonary or systemic circulation, or of the presence of associated disease.

For the past year I have had visiting my clinic a man 25 years of age, a painter by occupation, to whom some five years ago, a most gloomy prognosis was given, after one examination, and that, from the description, not very carefully accomplished. He had been suffering previously to his coming to the clinic with palpitation, dyspnea and syncope, symptoms consequent on lessened power in the left ventricle. There was but very slight edema. The original lesion was a mitral valvulitis of a regurgitant character caused by rheumatic infection and signalized by a loud blowing murmur heard over the apex and conveyed behind. There was present a moderate amount of dilated hypertrophy with the dilatation in excess. These symptoms had demonstrated themselves for years, and the very chronicity of the disease, combined with a careful uranalysis, and a searching investigation into his family history, led me to give a rather favorable prognosis.

Under appropriate treatment the heart has regained much of its lessening strength, the palpitation has disappeared, and his general condition so much improved that he has followed his occupation, that of a painter, for the past six months without intermission. The element of hope generated in this man's heart, by the rapidity with which his subjectively alarming symptoms were overcome, and the constant iteration of the fact that he would not "suddenly drop dead," as had been intimated to him, was not the least among the therapeutic factors which led to his partial recovery.

If at times the physical signs claim more than their share of importance, there are other occasions in which their significance is minimized, except to the skilled observer. This is particularly noted in men who have passed the meridian of life, whose general nutrition is failing, and in whom are to be found an occasional attack of palpitation and syncope accompanying a feeble heart. These are dangerous symptoms and frequently portend a fatal termination from fatty degeneration. There is a third class found among those who are over-indulgent at the table, and whose systems, now and then, are swept by a wave of uric acid, and in whom gouty manifestations have not had sufficient time to develop those permanent changes associated with that disease. At the height of the attack physical examination will disclose an accentuated aortic second sound, accompanied by a passing insufficiency of the aortic valve with high tension and marked arterial pulsation. If one was to be guided solely by these signs, an inaccurate diagnosis would follow, with a very faulty prognosis; for the administration of suitable remedies rapidly divests the situation of its seriousness, and on the following day the vestiges of the storm are to be found in a headache, subsequent to the disappearance of the tension and other exaggerated symptoms.

In illustration let me briefly refer to the following case: Mrs. G., 32 years of age, with an exceptionally good personal and family history, was seized with an attack of acute indigestion, which rapidly developed into so-called "biliousness." She was a very hearty eater, and particularly fond of sauces and condiments. She had experienced previously several attacks of indigestion, but none so severe as the present. Her temperature was 104, pulse 120, bounding in character and with well-marked tension, the carotid pulsation being clearly perceptible. On auscultation, I discovered a marked insufficiency of the aortic segments, in fact a characteristic aortic regurgitation, so far as the physical signs denoted. I prescribed the usual diet and remedies and the following morning these symptoms of "pernicious activity" had entirely disappeared, and careful auscultation since, on different occasions, has failed to reveal anything abnormal about the heart.

The history of the first attack of endocarditis should always be thoroughly appreciated by the practical physician. It determines the length of time the affection has existed, as well as its tendency toward development. When the morbid condition originates in an acute specific disease, such as scarlet fever, and where a recurrence is not probable, the outlook is more favorable than when it arises from rheumatism, where each new attack may mean an extension of the endocarditis, or new foci of disease where previously none existed. It is impossible to determine during an attack of acute endocarditis what the ultimate outcome will be, whether it will rapidly disappear, and leave no recognizable traces of the acute inflammatory action, or continue for years and finally develop the sequelæ of advanced disintegration of cardiac muscular tissue. There can be no question, for it is a fact frequently confirmed by clinical experience, that resolution, with absorption of the inflammatory products, takes place with consequent disappearance of all physical signs. A murmur may persist for years, and gradually disappear, a fact that should have some weight with candidates for life insurance, who are gauged, naturally, by present conditions, the probabilities of the future disappearance of the murmur being altogether too vague, with the present standard of statistical calculation. The distinction which it is usually most important to ascertain, is between lesions originating in acute endocarditis which may be stationary, and possibly, retrogressive, and those produced by chronic, inflammatory, or degenerative changes, which are inevitably progressive.

However, I do not intend at the present moment to deal with the very interesting question of cardiac prognosis as applied to life insurance, but will postpone its consideration for some future occasion.

The more common results of endocarditis are the persistence of the inflammatory products; the young connective tissue develops into fibrous tissue, which as it develops contracts, and the valves becoming more or less thickened, their function is disabled. But while two hearts may be pathologically identical, clinically they may be widely apart. Some hearts are painfully susceptible to renewed developments of endocarditis with every fresh attack of rheumatism. There are others to which the first attack of endocarditis would appear to provide a certain safeguard, for no matter how many times the system may be involved, subsequently to the first invasion of rheumatism, the endocardium appears to be invulnerable.

In some hearts the area of endocardial inflammation involves but a small portion of the valve, and when the acute manifestations have passed away, the further progress of the disease is of an exceedingly chronic character. In others not only the endocardium, but the muscular tissue of the heart itself becomes engaged in the inflammatory process. In this connection it may be noted, that frequently in patients afflicted with inflammatory rheumatism, an increased area of cardiac dulness does not always mean pericarditis, for we have frequently a dilatation of the heart due directly to the rheumatic toxemia. This is especially noticeable in children, and often before the dilatation passes away, there is a recurrence of the rheumatism, further intensifying the original dilatation, and in time producing retrograde changes in the myocardium which gradually terminate in cardiac failure. This class of cases is frequently found with supposed lesions of the mitral valve, generally of a regurgitant character. We are apt to exaggerate its importance by ascribing the dilatation to its influence. But in all probability the greater part of the dilatation resulting from acute rheumatic attacks is not really due to the co-existing mitral regurgitation, but that both dilatation and regurgitation are persisting effects of the acute attack, the former due to its poisonous influences on the cardiac muscle, the latter to the synchronous endocarditis. I remember during my last year at the University and while on temporary service in Bellevue, having such a case come under my observation. In life there was found a loud blowing systolic murmur at the apex. accompanied by chronic dilatation. The patient finally succumbed to pneumonia. When the case came to autopsy, performed by Welch, now of Johns Hopkins, we found to our great surprise the slight damage to the valve was entirely too limited to satisfactorily explain the dilatation. The principal cause here of that condition was undoubtedly the original rheumatic attack. We should be on our guard then in attributing too much importance to the presence of a systolic apex-murmur, from the standpoint of prognosis, for more depends on the size and strength of the heart, the recognizable modification of structure to be sought for in the perversity of function, rather than in the close consideration of an individual symptom, no matter how prominent.

Let us suppose that the patient comes under observation some time after the original attack of endocarditis, it may be months or years, two, five, ten years, and that a murmur still exists indicating that at some time in the past the heart has been hampered in its work. Prognosis, as has been said, then becomes a problem in proportion. If the heart is in a certain state at the end of a certain time, what will be its condition cæteris paribus in six months or in six years. The longer the interval that has elapsed since the acute inflammation, with more certainty can this be predicted. If in the same period one patient has arrived at the stage of dropsical effusion while another has a much enlarged heart which can still, however, overcome the obstacle to its work; and another is unconscious of disease, and there is but slight increase in the hypertrophy, and in yet another no change whatever has occurred, the inference can be drawn with a great amount of certainty, that as it has been in the past, so will it probably be in the future, disease that has advanced will continue to increase, that which has been quiescent will remain so still, and through the whole series the foundation of prognosis is time, and the changes it has wrought. The question as to sudden death is almost invariably asked by those who are personally aware of heart disease, and it is the duty and high privilege of the physician to be able to relieve the mind of his patient, that in all cases of valvular diseases, with one exception, that of aortic regurgitation, sudden death is a contingency which may practically be left out of consideration. Apart from this liability, aortic insufficiency is much more serious than constriction at the same orifice, because of the tendency to over-distension of the ventricle during diastole. In stenosis the arteries are scantily filled, and anemia of the brain is apt to develop on the slightest exertion. Those suffering from a single valvular lesion often do better so far as immediate relief is concerned, by having an incompetency of another valve added to that already existing. Thus in aortic regurgitation there is less liability, for the time being, to sudden death if there is a subsequent mitral incompetency developed. The regurgitation through the mitral orifice during the ventricular systole lessens the amount of blood passing into the aorta and therefore the force which distends the ventricle during the succeeding diastole.

In an analysis of 400 cases in which on post-mortem examination it was found the heart had undergone marked changes, in 151 there was definite valvular stenosis, without sudden death in a single instance, in the sense of the sufferer being overtaken by death while in apparent health; of aortic insufficiency there were 38 cases, 3 were brought to the hospital dead, a fourth died suddenly in the hospital; in 6 more the final symptoms came on abruptly and were rapidly fatal. Of 53 cases of mitral stenosis, only 1 was brought in dead. Those of mitral insufficiency or regurgitation were 49 in number; of these 2 may be said to have died suddenly, but both had serious symptoms and were under treatment in the hospital at the time, and in both the pericardium was adherent; in 3 more a sudden attack of dyspnea set in and proved rapidly fatal. Under the head of hypertrophy and dilatation only 2 sudden deaths were directly attributable to the state of the heart. When we come to fatty degeneration, the story is very different. In 9 out of 38 cases the termination was sudden; it is in effect to fatty degeneration that heart disease owes much of its terror of sudden death. It is the accumulation of years of insidious changes whose manifestations are in the beginning quite imperceptible, but they have a tendency to grow more intense from the persistence of the original cause. The nutrition of the heart in these cases is markedly defective, and, unfortunately, in the earlier stages not recognizable, though a pulse of low tension and irregular with an occasional attack of dyspnea should put us on our guard, particularly in those who have passed the meridian of life. Of course, it is, I trust, fully understood that I do not refer to the acute manifestations of fatty degeneration, which may be found in idiopathic anemia, or in the course of phosphorous poisoning, but to cardiac degeneration of a fatty character, as we generally understand the disease. Personally, I do not believe this terrible disease exists at all in the proportion to which it attains in the mind of the physician, and I say the mind of the physician advisedly, for there it has its existence oftentimes, rather than in the heart of the patient. It is not an easy matter to make an accurate diagnosis of fatty degeneration of the cardiac muscular tissue, though it would seem as if some physicians have an intuitive perception of the changes taking place after a superficial examination. It should also be remembered that in autopsies where frequently fatty degeneration is supposed to exist, it is really rapid decomposition which produces an appearance of the pathological changes of that malady in the muscular fibers of the heart. I have dwelt on this affection at some length, because I have heard from others of its frequency. Of 255 cases of heart disease of all kinds which we have treated in our clinics in St. Joseph's Hospital, at the West Side German Dispensary of the New York School of Clinical Medicine, and in the Outdoor Department of St. Vincent's Hospital, as well as in private practice, during the past two years and a half, I find but 2 cases of fatty degeneration recorded, 1 occurring in a male, 64 years of age, the other in a man of 82; the symptoms at least would make a clinical diagnosis of the disease possible.

Of the aortic lesions there were aortic insufficiency 18, mitral insufficiency 95, aortic insufficiency and stenosis 45, mitral insufficiency and stenosis 74, 1 case of lesion of pulmonary valve, 6 of pure aortic stenosis and 14 of pure mitral constriction. Lesions of the right side of the heart are relatively rare, and they can scarcely be considered independently of affections of the heart or of the lungs.

It may be interesting in this connection to mention that mitral stenosis is much more frequently found in women than in men. Out of 53 cases, 38 were females, the balance in males. On the other hand, aortic insufficiency is more frequently met with in men. Out of 36 cases, 30 were in males, 6 females. I am also led to believe from my researches into the territory of cardiac diseases, as well as from personal observation, that pure mitral stenosis is a comparatively rare affection, and the same statement, with perhaps somewhat milder limitations, may be applied to pure aortic stenosis. In an analysis of 33 cases with pure mitral disease, the average age was 29, while the average age of 14 patients in whom the aortic valves were affected either with or without mitral disease was 41. This is a further illustration of the well-known fact that mitral lesions occur early in life as a result of endocarditis, while aortic lesions are found later, frequently the result of atheroma. In 27 out of 50 cases, there was a clear rheumatic history. In 5 cases the rheumatism was found associated with scarlet fever. In 23 cases there was no history, but this does not invalidate the supposition that rheumatism was the original factor, as we are apt to forget the diseases of infancy and early childhood.

Different affections of the valves have, inherently and mechanically, different degrees of tendency to the production of structural alteration. The time of life at which the lesion of the valve takes place is of great significance, a given valvular affection established in youth is apt to be survived with great hypertrophy, though it must not be overlooked that valvular disease appears to be more serious in early childhood than a few years later. The heart can not keep pace with the active growth of this period of life, and answer to the demands of hypertrophy, in whose development time is an important factor, as well as the mode of living.

The period after the occurrence of the valvular change, at which active exercise was undertaken, will have great influence on the condition of the cardiac walls and cavities.

In aortic obstruction there must be either increase in the propulsive power of the heart or diminished rate of circulation. The increased power is gained by hypertrophy, and I regard a direct aortic murmur accompanied by hypertrophy to be more serious than when the combination is not found, because in the former case the mechanical difficulty is sufficiently great to call for cardiac development. On the other hand, in aortic insufficiency a certain amount of blood returns into the ventricle at each systole, an increase in the force of the contracting power would not overcome this, but an increase in the capacity of the left ventricle brings about the desired result and thus helps to compensate for the regurgitation. Dilatation, which under all other conditions is injurious, is thus actually a compensatory change in aortic incompetency; it is totally different from the dilatation which is now and then met with as the result of structural weakness or degeneracy of the cardiac walls. There is also a demand for the exercise of force in the additional quantity of blood to be pumped at each systole, so in addition to the dilatation we must have hypertrophy. The case is different with mitral regurgitation. Here we do not find the same degree of dilatation or hypertrophy in the left ventricle, while in mitral stenosis there may be actual contraction. It is in aortic incompetency that the extremes of dilatation and hypertrophy of the left ventricle are met with, and they are apt to be the measure of the regurgitation in the absence of symptoms, such as breathlessness on slight exertion, faltering action of the heart, with tendency to faintness and vertigo.

In advanced life mitral regurgitation is common without actual lesions of the valves, and may come on suddenly after illness or overstrain, or approach insidiously. Mitral stenosis is the valvular affection which independently of inflammation or ulceration most frequently gives rise to arterial embolism.

Mitral stenosis is the gravest of all cardiac lesions, and especially if it develops after middle life. So far as the physiognomy of mitral stenosis is concerned, it is very deceptive, the subject of this affection frequently presenting every appearance of perfect health. Let me close with this interesting aspect of heart disease by stating, that the obliteration of the second sound is an element of pronounced gravity.

With aortic regurgitation is frequently associated angina pectoris, that terrible disease which Balfour has described, "as if a mailed hand grasped the chest in the cardiac region and squirted through its fingers flashes of excruciating agony," a disease in which the cumulative tortures of a thousand deaths are concentrated in one. The patient liable to such seizures is constantly walking on the edge of a precipice, not knowing the moment when he will fall into the depths below. It can not be said to be a disease-entity, as it is associated with so many conditions which give rise to abnormal distension of the cavities and consequent stretching of the nerve fibrils beneath the endocardium. The prognosis of true angina is extremely uncertain, and the wise physician will ever be chary of expressing a definite opinion.

CONCLUSIONS.

1. When a heart murmur is discovered, do not give a gloomy prognosis on that simple fact alone; consider the condition of the cardiac walls, the probable length of time the lesion has existed, the presence of dilatation or hypertrophy, or both combined. The occupation and temperament of the patient are very essential factors in the prognosis. Each individual is a law unto himself, and though certain general principles may be established as a basis on which to build a working prognosis, remember we have no real means of recognizing the strength of the individual heart except its power of resistance against the poisonous effects of alcohol and tobacco or the inroads of the acute or chronic diseases, or the stress of laborious occupations, or the debilitating influence of prolonged exposure. The diagnosis should be complete, the prognosis tentative. Or, as a distinguished English colleague has said: "Give your prognosis on the best suppositions, treat your patient on the worst." (Allbutt.)

2. Remember that murmurs do not invariably mean endocarditis, and a prognosis based simply on the presence of a murmur would be rank injustice to the patient, and demonstrate incapacity on the part of the physician. As a skilled observer has well stated: "With an apex-beat in the normal situation, and regular in rhythm, the auscultatory phenomena may be practically disregarded."

3. To those of us who are interested in life-insurance work, this is of great importance. We wish to be just to the applicant, and at the same time, do our duty toward the company. The fact that a man has a murmur at the apex, of which he is entirely unconscious, whose heart is doing its work thoroughly despite the existence of the lesion, whose occupation is not of an adversely laborious character, who has passed that period of life when acute rheumatic infection is liable to stimulate into fresh and renewed activity the latent inflammatory products of an ancient endocarditis should be factors to guide our judgment as to the probabilities of the future and prompt us in recommending for him a policy commensurate with the degree of cardiac inefficiency.

It should not be forgotten in this connection that a presystolic murmur does not always indicate the most serious of all lesions, viz., a mitral stenosis, nor has a so-called musical apex-murmur any particular significance in prognosis, indicating, as it does, the passage of a stream of blood through a small aperture in the segment of a valve.

4. From the standpoint of longevity, aortic stenosis is a favorable lesion, and the writer must differ from some authors who state that it appears for the most part after middle life. It is found at that period when a man should be at the highest point of physical capability, between 30 and 50. It is true that it is frequently present as part of a general decay, and then develops in consequence of atheromatous changes taking place throughout the system, but it is more frequently present than has hitherto been suspected without such pathological manifestations being present.

5. Do not inform a young man between 18 and 25 that he has heart disease because you discover some hypertrophy with no complications, the result in most instances of active exercise. The writer knows of one individual whose heart is "athletic," a splendid specimen of manhood whose existence was embittered by the thought of heart disease communicated by a careless and injudicious physician. In this condition, it is, of course, understood that a careful consideration will be given to a large number of causes, independently of diseases within the heart itself, which may produce hypertrophy, for example, that typical enlargement of the heart co-existing with an interstitial nephritis.

Never hesitate to ask a patient to return for further examination, as the condition then may be entirely different from the first examination. There are more snap "diagnoses" made in the realm of cardiac affections than in the study of diseases in any other portion of the body.

DISCUSSION ON PAPERS OF DRS. SOLIS-COHEN. BISHOP AND MORRISSEY.

DR. FRANK BILLINGS, Chicago—These papers cover so much ground and there are so many who would like to discuss them that I will limit my remarks to a few subjects only. I desire to say something concerning acute endocarditis. This is a disease which is usually recognized, especially when classic. When acute in manifestation it presents many of the phenomena of the typhoid state and is accompanied by many definite anatomical lesions. But it is not always so; acute endocarditis, or subacute endocarditis, especially if of the vegetative or ulcerative kind, is not so easily recognized. All of you who have followed such cases through the hospital and to the autopsy table have recognized that fact, I believe. It has only been recently in the wards of the County Hospital that I have seen two cases of this kind. A Russian, 32 years of age, came into the ward suffering from anemia, with the consequent weakness, with an irregular type of fever. The anemia was apparently secondary and was very marked. The red cells fell as low as 2,000,000 to the cubic millimeter, and the hemoglobin to 30 per cent. Associated with this was a murmur over the heart at its base; this murmur was characteristic of aortic regurgitation. Under rest treatment, quiet in bed, the patient improved and was finally allowed to get up. In two weeks a relapse occurred; an examination showed, in addition to the murmur referred to, an aggravation of the anemia and there were microscopic amounts of blood in the urine. The spleen was palpable. The blood-pressure was low. Then for the first time I suspected the possibility of an acute endocarditis. The man died suddenly from hemiplegia. The postmortem revealed a subdural hemorrhage and marked endocarditis involving the aoritic valve. Another thing which we suspect when there is an ulcerative endocarditis, with a palpable and perhaps tender spleen, with blood in the urine, is multiple infarcts, but there was none in this instance. The hematuria and palpable spleen were due to a passive hyperemia. Recently there died in the hospital a patient who was in my care for a long time, but, who was under the care of Dr. Preble at the time of death. This patient lived for months with an ulcerative endocarditis, and emboli were constantly being sown from the heart. The patient was always clear neutrally. The fever was not high and usually irregular in type. These two cases illustrate the fact that ulcerative endocarditis is not always classical in its symptomatology, and that it is sometimes difficult to recognize. In the Presbyterian Hospital recently was an Italian, unable to speak English, who came in in a typhoid state. The temperature ran on the second day to 105, but it suddenly fell to normal. The blood was examined for typhoid fever, for malaria, etc., but ordinary search did not reveal the source of the disease. The heart was weak and the blood-pressure was low. Associated with this was a murmur heard part of the time only over the heart. There was a marked accentuation of the second aortic sound. Because of the low blood-pressure, I made a probable diagnosis of an ulcerative endocarditis. The patient died, and the post-mortem revealed an endocarditis and incompetency of the aortic valves; and yet there was an accentuation of the second aortic sound. This patient was in the typhoid state, with a low blood-pressure and had, part of the time, a murmur over the heart. Ulcerative endocarditis is a disease difficult to recognize and the general symptoms or condition are quite as important as the local signs. Among the local signs is a marked anemia, which occurs in those cases due to a toxemia. Another important sign is the low blood-pressure.

The next subject that I should like to refer to is not valvular lesions but myocarditis. This occurs in all valvular lesions sooner or later, but I shall not discuss that which occurs in valvular lesions. It also occurs in many toxemias and in all infectious disorders. It may be due to severe typhoid fever, and to pneumonia, and is recognized because of the weakness and failure of the heart. Myocarditis may be due to chronic toxemias, which are, in turn, due to gouty conditions and auto-intoxication. These cases of myocarditis present conditions which do not make the diagnosis easy. There are often no local signs. Such patients present nervous phenomena; they are very irritable. The business man changes in his disposition; instead of being earnest he may be frivolous, or he may not be able to grasp important business situations as he once did; or, instead of his mental powers being disturbed, there may be loss of digestive power. The diagnosis may be made of gastric disorder dependent on a weak heart. These things all become aggravated in a short time and the patient complains more after eating, when he has some fullness about the epigastrium, or some dyspnea. The dyspnea later increases and occurs when he is talking business or when excited. The compression then becomes actual pain. The pulse changes in its character and, perhaps, may not be more rapid, but slower. Congestions occur easily and there is associated malnutrition. Finally, dilatation occurs and associated with this all the phenomena that go with heart disease. The practical point is that, in these cases, especially of myocarditis, they require early attention. Frequently we can remove the cause and restore much of the heart power.

Dr. DeLancey Rochester, Buffalo—The statement has been made by Dr. Billings, and I understood that Dr. Davis also made it, that acute ulcerative endocarditis was more frequently recognizable than not. I think it is most difficult to recognize. I think it is more frequently mistaken than any other form of infectious disease. I state this on authority and on personal experience. My personal experience has extended over fifteen years, and has occurred in three hospitals. During this time there were five cases of acute ulcerative endocarditis under different observers, that were not diagnosed until after death. The diagnoses in these patients were various. That the diagnosis may be made by careful study of each case is possible, and therefore these cases should be carefully investigated. There is one case that illustrates this fact; this patient was brought into the hospital, the General Hospital of Buffalo, on the surgical side for operation for an appendicitis. She was operated on and the appendix, although there was nothing diseased about it, was removed. The chief complaint was pain in the abdomen. There was a certain amount of fever which did not subside after the operation. She was removed to the medical side. The abdomen was distended and she still complained of pain in it. Careful manipulation and study of the case indicated a point of pain on the left side and in the upper zone, but toward the left chest; yet, nothing could be found beyond that but a distention of the bowels. This was relieved by the use of asafetida per rectum. The fever persisted. A careful study of the blood was made, typhoid fever having been suspected. There was no Widal reaction. There was a large amount of indican in the urine. Ehrlich's reaction was thought to be present, although there was some doubt about it. There was, however, on examination a marked leucocytosis. When we can find a very marked leucocytosis, of considerable degree, with no evidence of localized collections of pus, we should suspect the presence of ulcerative endocarditis. So far as an examination of the heart was concerned there was no murmur whatever and no embolism occurring in any part of the body. The patient died undiagnosed, and the autopsy showed an ulceration on the ventricular side of the mitral valve, which had penetrated through into the other ventricle.

I believe that changes in the myocardium are exceedingly serious and are frequently overlooked. In chronic myocarditis we should take into consideration the general condition of the patient more than the local condition, so far as the heart is concerned; this means the condition of the pulse, the general nutrition of the patient, the condition of the arteries particularly, and also the condition of the heart, of which we may have more or less dilatation, more or less enlargement, and weakness of the sounds. So far as the various valvular lesions are concerned, two are serious, i. e., aortic insufficiency and mitral stenosis; of these aortic insufficiency is the more serious. The diagnosis of this condition depends on the diastolic murmur. Whenever I hear a diastolic murmur I feel that the case is always serious. Of course, in mitral stenosis the murmur may be decidedly diastolic. Right here, in regard to mitral stenosis, I wish to state that a presystolic murmur is less serious prognostically than a rough diastolic murmur heard in the same place. But, the conditions on which the prognostic value in these valvular diseases depends are not so much the local conditions of the heart as the condition of the general circulation. The condition of the arteries particularly is of great prognostic value; the more pronounced the changes there the worse prognosis must we give. Dr. Morrissey spoke of murmurs that had existed for a number of years; in my opinion a murmur that has existed a number of years is an organic murmur due usually to change in the ability of the valve to close the orifice; either a decided change in the valve itself, or the myocardium. If it has existed for several years and then disappears it is a much more serious matter than if it continued to exist; it shows a more marked weakening of the muscle itself.

Dr. James B. Herrick, Chicago—The tendency to-day is to pay more attention to the muscle of the heart than to the valves, and I will place myself on the side of those who so practice. The time has passed also, when we make a diagnosis of lesions of the heart merely on murmurs that may exist. We have to take into consideration the secondary changes that follow each valvular lesion; the size of the heart; the alteration in the aortic and pulmonic tones; the condition of the pulse, both as to volume, tension and irregularity; the peripheral tone. All these things should be taken into consideration before determining as to the nature of the valvular lesion, whether it is organic or due to dilatation of the heart, or whether it is an accidental or functional murmur. More than that, we can not rest content with making a diagnosis of valvular lesion, but we must go further and ask what is the condition of the heart muscle. This is very important, because, as we have learned from the several papers read and the experiences related, such patients may live with apparently serious valvular lesions for years provided the muscle of the heart is capable of doing its work. This was impressed on me when I was called a few years ago to see a man, 67 years of age. As I was listening to his heart he said: "I know I have heart disease; Skoda told me so, but said with care I might live to be an old man." He had a valvular lesion which more than thirty-seven years before had been recognized by Skoda. In the clinic I recently saw and presented a case of aortic stenosis where the history dates back twenty-five years and only now is compensation beginning to fail. The principal question is how long may the muscle of the heart do its work, and what is the condition of the myocardium?

I certainly find it difficult in a case of acute rheumatism to speak positively of the condition of the myocardium. If I understood Dr. Rochester correctly, he stated that in cases of acute rheumatism he can diagnose an acute myocarditis by the endocardial murmur. It seems to me there is great difficulty in diagnosing acute myocarditis either in the course of an acute rheumatism or other acute infectious disease. Perhaps here we use different terms. What one would call myocarditis another would possibly call acute parenchymatous degeneration of the heart. There may justly be some difference of opinion as to what is the significance of the murmur in acute articular rheumatism, whether it is a hemic or an accidental murmur, the murmur of an acute endocarditis or of a relatively incompetent valve, or of a true myocarditis.

I wish to mention, in connection with the diagnosis of chronic myocarditis, the importance of recognizing the etiological factors. And here I emphasize one fact already dwelt on, i. e., the importance of heredity. If we go back into the history of many of these cases we shall find striking instances of this, shown especially in the effects of sclerosis of the blood-vessels, in the early deaths from angina, cerebral hemorrhage, renal disease, aneurysm, etc. The symptoms in these cases of chronic myocarditis may be most pronounced, but occasionally cases are met with where, without preceding symptoms, there is sudden death. I have seen a man of 60 years die in his first attack of angina where there had been nothing previously to indicate the existence of heart disease.

In regard to the treatment of myocarditis there are two points to which I wish to call attention. Of the greatest importance is rest. And secondly, when in myocarditis dilatation has occurred, when all the evidences of marked incompetency are present, when death seems to be imminent, the patient cyanotic, with edema of the lower extremities, etc., bleeding is of great value. This treatment, with rest, will frequently restore temporarily the integrity of the heart.

Dr. Bertram W. Sippy, Chicago—Dr. Rochester has made the point that a leucocytosis occurring in an obscure case in which malignant endocarditis was suspected, was of great value in the diagnosis of that condition. A few years ago, it was supposed that leucocytosis occurred in all septic conditions; in the absence of an increased number of leucocytes, septicemia was not to be diagnosed. The more the condition leucocytosis is studied, the less constant appears to be its relation to the various infective processes. It is fairly well established that with the exception of typhoid fever, malaria, miliary tuberculosis and measles, leucocytosis is likely to be present in all acute infections. Sepsis is usually accompanied by a well-marked leucocytosis. Experience has shown, however, that even the severest sepsis may exist without an increase in the number of leucocytes. It has long been known that puerperal fever may be unaccompanied by leucocytosis. The same seems to be especially true of malignant endocarditis. Neusser, of Vienna, was probably the first to note that malignant endocarditis was prone to run its course without leucocytosis. Previous to 1895, he had observed six cases in which leucocytosis was absent. At that time, he was inclined to look upon the absence of leucocytosis as one of the characteristics of the disease. Since then I have observed four cases in which the leucocytes were not increased. A rapid reduction in the number of red blood-corpuscles, the presence of normoblasts and marked poikilocytosis are commonly found in malignant endocarditis.

Dr. Judson Daland, Philadelphia—During the winter I had the opportunity of studying a case of ulcerative endocarditis, which was also seen by Dr. Da Costa, who in this particular case, attached much importance to the presence of leucocytosis, the leucocytes numbering 40,000 to the cubic millimeter. It seems to me, however, that this sign will probably not prove to be of very great value excepting in ulcerative endocarditis unassociated with fever, as most cases show intermittent fever. The leucocytosis present could be ascribed to this cause alone, irrespective of what may have produced it. I was extremely interested in the case reported by Dr. Davis for the reason that he believed the source of infection to be through the intestinal tract. About one year ago I saw an instance where the disease had existed for a period of eight months; I saw the case about one month before death. The man was known to have been without the disease for years. Severe intestinal symptoms suddenly developed, after which the characteristic intermittent fever of ulcerative endocarditis appeared. It continued until death occurred eight months afterward. In that case we employed the antistreptococcic serum, first injecting 2.5 c.c., which was followed by a slight reduction of fever. A second injection of 5 c.c. was followed by distinct evidence of weakness. After this 10 c.c. were used, which was followed by such marked evidences of collapse that it looked as though the man would die. The serum seems to be of value in certain cases of ulcerative endocarditis, but it should not be administered in those cases which have advanced so far that extreme weakness has developed, as the serum is itself able to bring about fatal collapse even in as small a quantity as 10 c.c. I was much impressed with the references made in regard to the prognosis in heart disease. I recall a case of aneurysm of the heart occurring in a man apparently in perfect health until twenty hours before his death. This man had no symptoms of cardiac disease and was insured by an insurance company as a good risk. The autopsy showed extensive fibroid changes occupying the interventricular septal region, covering an area about the size of a silver half dollar. Further examination showed extensive atheroma of the coronary arteries. The cause of death was a thrombus in the right coronary artery. The case reported by Dr. Billings was symptomatically a counterpart of one that occurred in the University Hospital, where there was a marked anemia, there being less than 2,000,000 red cells to the cubic millimeter and a systolic murmur over the apex; the recurring pyrexia brought up the possibility of an ulcerative endocarditis. The autopsy, however, showed no ulcerative endocarditis, but pernicious anemia.

Dr. H. M. Fussel, Philadelphia—Other signs than cardiac murmurs are important in making a diagnosis of heart lesions. There is no question that students, and many men as soon as they leave college, believe that there can be no heart disease unless there are murmurs present; they also believe that unless there are heart murmurs present the case does not admit of any treatment. Of course, this is an error. The most common error made is that regarding the systolic murmurs at the base of the heart; it is almost invariably the case that when a student detects a systolic murmur at the base of the heart, he considers the individual suffering from an aortic stenosis. Of course, this is far from the fact. It is well known that serious heart lesions may exist without the presence of any murmur. A case occurred in my practice some years ago in which a man suffered from cardiac disease without symptoms of loss of compensation; during three or four years he was examined frequently and nothing was found in the way of a murmur. At the time of his death there was a dilatation so great that five fingers were admitted in the orifice; and yet there was no murmur.

The points in the treatment should be based on the condition of the pulse, whether regular, feeble, rapid or slow. Then one should consider the size of the heart, and I am sure many neglect to outline this organ. Any heart that extends from the sternum on the right to a point beyond the nipple on the left is certainly an abnormal size of the heart. The character of the first sound is very important. In cases of dilatation the first sound loses its muscular element and is very much like the second sound. The absence of the apex-beat frequently means loss of power in the heart muscle. Any accentuation of the first sound, a curious sharp short sound, is extremely indicative of stenosis of the mitral orifice. Regarding the point of Dr. Cohen about the so-called dilatation of the veins about the costal margins, I have often been asked by students what it means, and I always answer I do not know. I do not believe that it is a valuable sign in cardiac disease.

Dr. Robert H. Babcock, Chicago—I desire to add a word concerning the importance of the myocardial changes in heart disease. The profession has paid too much attention to the mere presence of murmurs as indicative of endocardial lesions, and shows a tendency to forget the condition of the myocardium. The physician is apt also to forget the condition of the myocardium in rheumatism. The following figures are certainly very instructive in this regard. Dr. Pointon examined 154 cases of deaths occurring in children from rheumatic heart disease, and he found, among these 34 instances of myocardial changes; in 13 cases the heart muscle was soft and pale; in 4 cases there was fatty degeneration; in 8 instances the myocardium was described as fibroid in character. Furthermore, in

92 of these cases there was marked general cardiac dilatation. These figures are exceedingly important as bearing on the prognosis of rheumatic heart disease in children.

There is nothing more difficult in the line of heart disease than to make a prognosis. I often say it is like betting on a horse-race; yet by nothing so much as by his ability to make a correct prognosis is a physician's experience shown. Leaving out of consideration all extrinsic conditions and limiting ourselves to a consideration of the changes in the heart, whether in valvular disease or not, I think we must all admit that the condition of the myocardium influences the course of any given cardiac disease. Take aortic regurgitation; there is a wide difference in aortic insufficiency of atheromatous origin from that of endocardial origin, or an aortic regurgitation developing as a result of endocarditis at a period of life when myocardial degeneration is already present as shown by the condition of the peripheral arteries. It is in these cases particularly that the career is short and death is sudden. So it is with atheromatous mitral lesions. We know when the mitral disease is the result of a sclerotic process that these are the cases in which the prognosis is grave and there is little hope of re-establishing compensation when once it is broken. This is contrary to the experience found in mitral disease in the young when due to an endocarditis; in such compensation may be frequently broken and restored, in part at least. It is not so when the myocardium is diseased.

DR. JOHN A. WITHERSPOON, Nashville, Tenn.—It is extremely rare in my experience that an aortic stenosis kills by degeneration of the heart muscle itself; it is due to a degeneration in the blood-vessel walls, usually those in the brain, rupture causing death. Along with this we may have valve lesions with murmurs, but with the heart muscle little affected; nor does the condition of the valves of the heart affect the prognosis so long as the heart muscle is capable of performing its function. Regarding the treatment of organic heart lesions, unless compensation is broken, it is malpractice to treat that heart, with medicines, like digitalis. Hygienic care and strychnin are useful.

DR. S. SOLIS-COHEN, Philadelphia—Dr. Fussell doubts my explanation of the costal fringe. I distinctly said and now repeat that this sign is not infallible. I have seen it in many cases in which I could find no heart lesion. Nevertheless it is one of those signs leading one to suspect that there may be some undemonstrable disease of the myocardium. If it occur in a patient who has a persistent enlargement of the liver, or who shows a tendency to recurrent enlargement of the liver, we are certainly justified in considering the patient at least a cardiac suspect. In regard to murmurs, valvular murmurs are not the only organic ones. We may have a myocardial organic murmur, or a myocardial functional murmur. Disease of the papillary muscle, as well as disease of the muscular fibers of the ventricle or the auricle, may mechanically interfere with the closure of the valves and give rise to the phenomena of insufficiencies.

DR. LOUIS FAUGERES BISHOP, New York City—In regard to the question of loud murmurs, I wish to allude to a case of my own in which an autopsy was performed a short time ago. A patient was brought into the hospital and promptly died. There was a loud murmur present but the valves were normal; there was simply dilatation. Dr. William H. Thompson, of New York, reported a case in which there was an extraordinary murmur over the heart due to dilatation occurring in a muscular man from sudden exertion. It seems to be true that loud murmurs do occur from dilatations. It is not always possible to make a diagnosis before death in malignant endocarditis. I would refer to a case seen last winter in which diagnosis was obscure but where I believe there was septic disease in which the kidneys had participated. The conditions were very obscure. That patient had a murmur, but the symptoms were never prominent. At the autopsy I found the valves almost destroyed. This patient had been bed-ridden, kept perfectly quiet, for which reason the murmurs were not marked.

SURGICAL ASEPSIS OF THE URETHRA AND BLADDER.

WITH DEMONSTRATION OF A DEVICE FOR THE PURPOSE.*

FERD C. VALENTINE, M.D.
Professor of Genito-Urinary Diseases, New York School of Clinical Medicine; Genito-Urinary Surgeon, West Side German Dispensary; Genito-Urinary Consultant to the Metropolitan Hospital and Dispensary; to the United Hebrew Charities, etc.
NEW YORK CITY.

In view of the impossibility of scrubbing, soap-poulticing and rescrubbing the urinary tract; of the infeasibility of washing it with ether, alcohol, or antiseptics sufficiently strong to kill bacteria, it must be confessed that efforts to obtain surgical asepsis of this region remain still within the realm of remote hope. The problem, therefore, is how we may attain, as near as possible, an approach to asepsis of the field of operation. Until about seven years ago, surgeons did their best to this end with urinary diluents, with the administration of drugs by the mouth, in the hope that the antiseptics therein contained would be carried through the bladder and urethra, or that in the changes the drugs would undergo in the organism, urinary antiseptics might be evolved; and by washings of the urethra and bladder with mild antiseptics by means of capacious syringes. These methods have their evident shortcomings.

Urinary diluents and drugs per os, even if they could fully perform all that is wished of them, would no more than act intermittently, i. e., only at the moments of urination. But as they can not, except during instants, unfold the urethra, they can not at the very best exercise more than a superficial and evanescent local effect. I would not, however, proclaim them useless; on the contrary, they are valuable adjuvants to approaching asepsis, so necessary a concomitant to instrumental ingression.

The topical efforts made to cleanse the urethra by means of even large syringes, are necessarily limited by the mechanical difficulties that beset such work. The irregularities of even the normal urethra place its expansions behind normal or abnormal coarctations beyond the effective reach of flushings which can not be otherwise than of irregular force when administered by a piston syringe. Besides, the inevitable intermittence in these flushings materially curtails their effectiveness. Manifestly, then, the local endeavors required a method whereby these and other self-evident defects could be overcome.

As far as I can learn from a most thorough search in literature, it was my good fortune to be the first to propose, seven years ago, that all invasions of the urethra and bladder should be preceded and, whenever practicable, followed, by copious irrigations, at least of the urethra. It would be an insult to surgical intelligence if I claimed better asepsis for my instruments and hands than others attain, and it would be beyond the province of this effort to discuss the etiologic factors of urethral fever. The experience of the past seven years, however, during which I have never omitted irrigations after instrumentations, has fully rewarded me and those who follow the method I proposed. The conjoined experiences are not small in number and their outcome is that there has not been a single case of urethral fever to report. Among these were patients who before had been treated by men whose scientific attainments and skill I unhesitatingly envy. Not a few of these patients warned me that even an exploration of the anterior urethra, most delicately conducted by the finest possible instruments, was invariably followed by fever. I irrigated their urethras before and after instrumentation, and not the slightest elevation of temperature resulted.

---

* Presented to the Section on Surgery and Anatomy, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

These irrigations hitherto were performed by means of the apparatus I devised for the purpose and which several excellent authors have complicated since then. I can not but applaud the compliment so bestowed. If one or another forgot that I originated the device, I am sure the memory of my priority slipped away in the enthusiasm for good surgical work.

But the urethral and intravesical irrigator had its limitations. Although much smaller and far easier of manipulation than the irrigators employed before it was devised, its use was necessarily confined to cases treated in the office. In this regard I have no regret concerning its efficacy. But time and experience have shown the need of another, much smaller, irrigator, that would occupy but a limited space in the instrument bag. Work, since June, 1899, on these requirements, together with those of simple construction, facile sterilization and easy manipulation, resulted in the auto-irrigator. Its essential features are a modified douche-bag, made in one piece with a tube 4 feet long, terminating in a shield and nozzle, the special finish of whose tip can not injure the most exquisitely inflamed meatus.

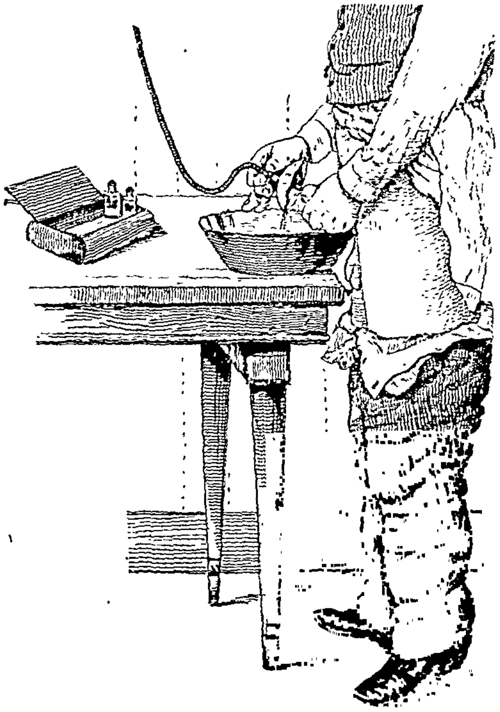

Fig. 1.—Irrigation in the standing posture.

The device throughout is so simple that the technique of its employment can not merit even a moment's description. As it has, however, other uses, and very important ones, I shall take the privilege of adding them to this paper when presenting it for publication. I may say now, though, that besides preparation of the urethra for instrumentation, this device proves of value in the treatment of such patients with gonorrhea as can not, for any reason, visit the physician as often as is necessary for systematic irrigations. It then serves as a substitute for such office-visits as can not be made. But I insist on being correctly understood by those who do not know me, that *this device is by no means intended to transfer to the patient the treatment of so dangerous a disease as gonorrhea.*

Another use in which the auto-irrigator proves convenient and effective is in those washings of the bladder and urethra which the physician may prescribe for patients who are obliged to catheterize themselves. While it would in every sense be better for the patient if this service were rendered by professional hands, it manifestly is impossible that prostatics be visited at least four times daily throughout catheter-life. These can be easily instructed to use the auto-irrigator, thus preventing the septic crimes that such patients continually commit upon themselves.[1]

To sum up the salient conclusions on the subject, I submit: 1. Perfect asepsis of the urethra can not be obtained by our present methods. 2. Urinary diluents and antiseptics by the mouth are limited in their action. 3. Washings with piston syringes, however large, must necessarily fall short of their purpose. 4. Asepsis of instruments and hands does not suffice to prevent urethral fever. 5. Urethral fever does not occur when instrumentation is preceded and followed by irrigations. 6. The irrigator I devised seven years ago and materially simplified since, effectively does the work required in the office. 7. The auto-irrigator, first exhibited before the Genito-Urinary Section of the New York Academy of Medicine at its meeting of March, 1900, and more fully demonstrated here to-day, enables the surgeon to perform urethral and intravesical irrigations anywhere. 8. The auto-irrigator is a useful adjuvant in the treatment of such gonorrheics as can not visit the physician with sufficient frequency. 9. The auto-irrigator offers the simplest method of preventing sepsis in those obliged to catheterize themselves.

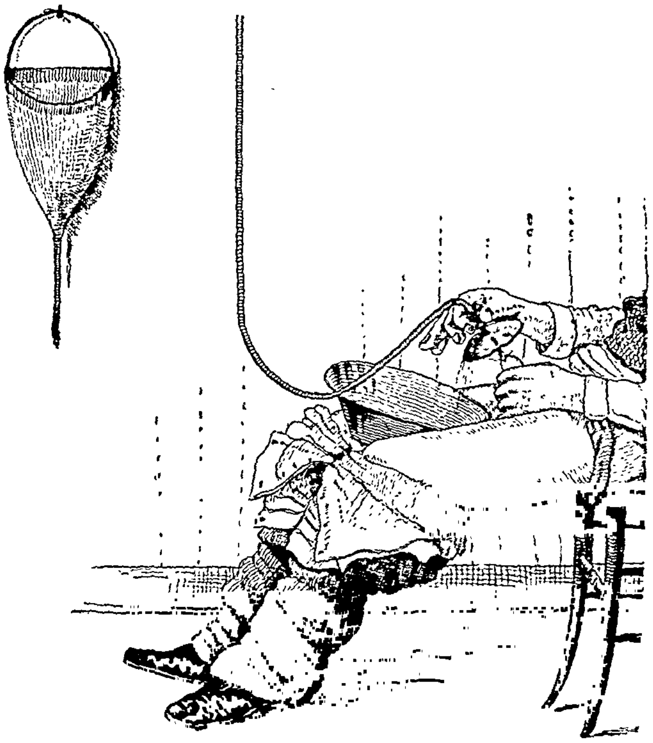

Fig. 2.—Irrigation in the sitting posture.

The foregoing brief synopsis of the purely surgical considerations of the use of auto-irrigations, suffices to describe its purposes before the Section. For the convenience of general practitioners, I beg to submit more

---

[1] The auto-irrigator is made by the Miller Rubber Manufacturing Company, Akron, Ohio.

92 of these cases there was marked general cardiac dilatation. These figures are exceedingly important as bearing on the prognosis of rheumatic heart disease in children.

There is nothing more difficult in the line of heart disease than to make a prognosis. I often say it is like betting on a horse-race; yet by nothing so much as by his ability to make a correct prognosis is a physician's experience shown. The auto-irrigator offers the simplest method of preventing sepsis in those obliged to catheterize themselves.

The foregoing brief synopsis of the purely surgical considerations of the use of auto-irrigations, suffices to describe its purposes before the Section. For the convenience of general practitioners, I beg to submit more detailed discussion of the subject, especially calculated for those colleagues who have had no special training in the cases in which it is applicable.

---

[1] The auto-irrigator is made by the Miller Rubber Manufacturing Company, Akron, Ohio.

Experience has shown that most cases of gonorrhea require irrigations twice daily for the first four days, then once daily for two or three days, and after that twice daily for three days. Those who obtain the most brilliant results owe them to the care and precision of their work. However enthusiastic they may be in consequence of such success, all must acknowledge that the necessarily frequent treatments are occasionally infeasible. Among the elements responsible for this are:

1. *The Patient's Occupation.*—Some men are prevented by their work from going to the physician's office twice daily, and some, because of their business, can not visit a physician even daily.

2. *The Patient's Means.*—Many men are unfortunately so situated financially that they can not pay for professional services twice daily, but having salaried appointments are not entitled to gratuitous services. Moreover, the hours at dispensaries are likely to be such that if men attended them they would lose their positions.

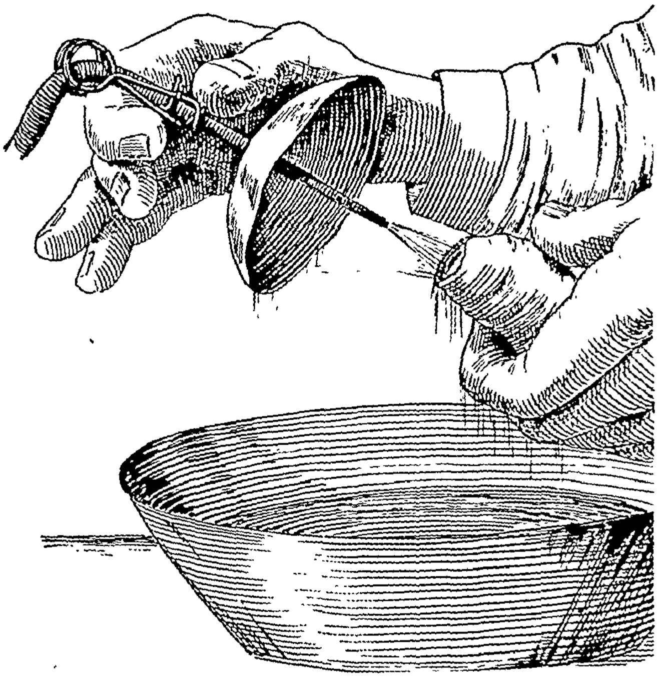

Fig. 3.—Preliminary washing.

3. *The Physician's Work.*—Busy general practitioners are exposed to being called from their offices at any time and thus are prevented from keeping appointments with their gonorrheal patients. If general practitioners referred such cases, which they are perfectly competent to treat, to a colleague, even if he is a genito-urinary specialist, their reputation would suffer, unjustly certainly, but none the less truly. Moreover, if for any reason a gonorrhea is not treated at the proper intervals, the purposes of irrigation are entirely thwarted. In such cases recourse was until recently had to the little piston syringe, with all its limitations. Some practitioners, I among them, endeavored to overcome the difficulty by ordering large six or eight ounce syringes. Owing to the difficulty of their management and their inadequacy these proved disappointing.

Much of the preceding can be applied to those men whose enlarged prostate obliges them to evacuate the bladder with a catheter. The cystitis that obtains in a majority of these cases requires bladder-washing after catheterism, before the catheter is removed. It is true that several two-way stop-cocks have been devised for the purpose, but they are somewhat complicated and their asepsis is by no means assurable.

To distinguish this little instrument from the apparatus known to the profession as the "Valentine irrigator," it is called the auto-irrigator. Its small dimensions and light weight make it unobjectionable to patients, who naturally have no desire to obtrude upon others the need of using it. Moreover, these characteristics make it an easy occupant of the instrument-bag, whenever urethral or intravesical irrigations must be performed by the physician at the patient's home.

The receptacle for the irrigating fluid has a capacity of 1500 c.c.—about three pints. Its wide top makes filling it easy, without any danger of soiling the floor with a solution that would stain, as for instance potassium permanganate. The back of the receptacle is flat. so that its contents are not likely to spill when the instrument is suspended from a wall. The outflow and shut-off are modifications of those described elsewhere.

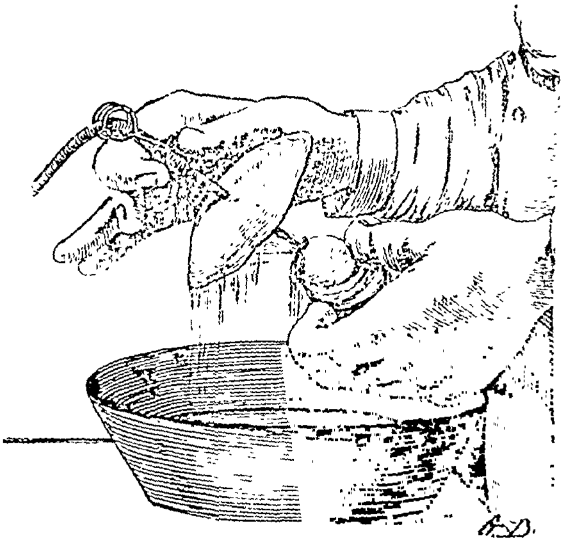

Fig. 4.—Irrigating the meatus.

In this connection, I again call attention to the peculiar finish of the nozzle, which prevents any injury to the most sensitive meatus in anterior irrigations. Moreover, its conical shape fits any catheter, and consequently renders bladder-washings by this means very easy when required for patients obliged to catheterize themselves.

With a view of facilitating my colleagues' work, I have formulated a series of directions, which experience has shown to be needed. They are necessarily exceedingly simple, with only so much explanation added as will enable laymen to intelligently follow the physician's orders. Naturally they will often have to be modified to meet the requirements of individual cases.

DIRECTIONS TO PATIENTS FOR THE USE OF THE *AUTO-IRRIGATOR IN GONORRHEA.*

These directions may appear complicated and perhaps difficult of execution. They are intended as suggestions for the physician only, and he will show the patient how to follow them easily and painlessly. Their complete and correct execution, even by an awkward man, requires less than five minutes. It seems desirable to be very explicit, so that a physician with little experience in the treatment of genito-urinary diseases may have no more difficulty in imparting the necessary instruction than one who does not need these directions. They naturally can apply only to the generality of cases; special circumstances may arise that will require essential modifications. Primarily, the patient should be impressed with the fact that his interest lies in strict compliance with his physician's orders, so that recovery be expedited and the dangerous complications and sequelæ of gonorrhea avoided. Quite frequently patients will relate that they or their friends successfully used this, that, or the other preparation in gonorrhea. It should be made clear to them that two instances of the disease may appear almost identical and yet require far different drugs in their successful treatment. It will be well to write the directions for irrigations for each case in addition to drilling the patient in their performance. Those that apply generally are noted below; the magisterial tone in which they are written is adopted for brevity.

1. Direct the patient to screw a cuphook into a door or window-casing, at the point he can comfortably reach without painfully stretching his arm. If irrigations are to be performed in the standing posture; the above point is sought while the patient stands. If irrigations are to be performed while the patient sits, he should measure the height of the hook in the corresponding way, i. e., seated on the chair intended for use during irrigation.

2. Have him fill the irrigator with boiling water and hang it on the cup-hook.

3. Show him how to fasten the catch of the shut-off and place the nozzle and shield so that the hot water which will then flow out, escapes into a basin or any other convenient vessel.

4. While the hot water is escaping, prepare the solution that is to be employed (see below, "formulary").

5. Order the patient to as completely empty the bladder as he can, and explain that the purpose hereof is to prevent immediately washing away that part of the solution which is left in the urinary channel after irrigation.

6. Direct the patient to drop his trousers and drawers to below his knees, and to fold his shirt and undershirt upward, so that they will not interfere with the work or become soiled by the fluid, if he should be careless in its use. A further good precaution is to tie one towel about his waist and another around each leg, to positively prevent his body being soiled.

This can be simplified by the use of a piece of rubber sheeting twenty by thirty inches, with a tape tied to each upper corner and a hole two inches in diameter cut through the part over the penis. The penis can then be drawn through this hole, and the irrigation so performed.

7. Release the catch on the clamp, which allows the latter to close, and so shut off the rubber tube.

8. The solution to be used is then poured into the irrigator.

9. Have the patient stand or sit—as may be preferable—before the irrigator or toward its side. If the patient is to stand, have him place a tin or enameled basin on a table at such a height that his penis will comfortably rest on its margin. If irrigation is to be performed in the sitting posture, have the patient hold the basin with his thighs, at such an angle that the penis lies on its margin. If it is preferred to have the patient use the apron-shaped rubber sheeting described above (see 6), have him fold the ends of the apron so as to conduct the flow from the penis into a pot, slop-bucket or water-closet with the seat raised.

It will be well to impress on the patient that he must never use a stationary wash-basin or bath-tub for this purpose, as it may expose others to dangers to health and life, which can be prevented by a few simple precautions. Any patient who is unwilling to guard others from this unfortunate disease could be placed under a species of quarantine with more reason than sufferers from yellow fever are now subjected to restraint in this climate. It is true that many men have survived many attacks of gonorrhea, but sad experience has shown that many have died from joint, brain, heart and abdominal diseases due to this affection. Therefore, a being who directly or indirectly communicates it to another is worse than a murderer.

10. Instruct the patient to take the penis in his left hand.

11. Place the shut-off in his right hand, and lightly press its bars with the thumb and index finger. This will let a slight stream of the fluid escape.

12. Order him to direct the stream against the outer surface of his foreskin, and to turn the penis about until all the outer part of the foreskin is thoroughly cleansed.[3] When this is done, have him direct a stronger stream to the opening of the foreskin, until its folds are clean. Then slowly draw back the foreskin and, as each part of its mucous (red) portion comes into view, have him wash it in the same manner. When the foreskin is entirely turned back, have him wash the glans, the coronary sulcus—depression around the head of the penis—and then the sulci—little depressions—at each side of the frenum—bridle.

13. After the foreskin and glans are cleansed, cause the patient to direct the rubber tip of the irrigator to the lips of the meatus—opening or mouth of penis—until they are entirely clean.

14. Show him how to press the left thumb and index-finger upon the upper and lower surfaces of the glans. This will open the meatus. Into the so opened meatus have him direct a gentle stream until it shows its clean, red mucous lining. Direct him to approach the rubber tip closer, as he gradually increases the force of the stream, until the soft rubber tip is within the meatus.

15. Direct the patient to continue pressing the bars of the shut-off slowly together until the full force of the stream is obtained, or if a disagreeable tension of the urethra results, have him check the force of the stream. Warn him that he must not wedge the soft rubber tip into the meatus so tightly as to prevent the outflow of the fluid.

16. With a little care the patient can be taught to so hold the tube and the penis that the fluid spurting from the meatus will be caught by the shield and directed to the pan or apron. Consequently no portion of the room, of his garments or his hands need be soiled.

17. Have him cleanse his hands thoroughly with a stiff brush, hot water and soap.

18. Show him how to soak a piece of absorbent cotton in bichlorid solution, 1 to 6000, or 1 to 10,000, and place it on the glans to cover the meatus, drawing the foreskin forward to hold the cotton. If his foreskin has been removed, or if it is too small to retain the cotton, teach him to fasten it in place with a two-inch gauze bandage. If bichlorid irritates the glans, order the patient to use a saturated solution of boric acid instead.

19. Impress on the patient that when he goes to urinate he must throw the cotton that has been on his penis into the water-closet or, better still, burn it. After each urination, he must apply fresh, clean cotton, as above directed, and wash his hands thoroughly thereafter.

20. Teach the patient to cleanse the irrigator after each irrigation, by passing boiling water through it; the shield and rubber-tip by first washing in hot water and soap, and then scrubbing them with bits of cotton soaked in strong bichlorid solution—1 to 1000. The instrument must be dried before it is put away, and the clamp should be forced open by means of the switch, so as to save the tube from wearing at the compressed point.

Throughout the foregoing instructions the patient should be especially warned that when performing any part thereof, he must not approach his hands to any portion of his face, nor use his handkerchief, lest by either means some of the discharge be carried to his eyes.

THE SOLUTIONS USED.

As circumstances may oblige the physician to instruct a patient in the preparation of irrigating solutions, I here note the directions in this regard, which are ordinarily used in such cases. Naturally the selection of the drug employed must be governed entirely by the special conditions that prevail in each case.

In the vast preponderance of cases, permanganate of potassium is as yet used in the treatment of gonorrhea. The most convenient form of using this drug is in

---

[2] Younger practitioners will do well to avoid the use of technical terms, even toward well-educated people. The method of giving directions to patients, that seems to appeal to the majority, is to use the ordinary expressions, coupled with correct anatomic designations, when they differ from those commonly employed.

2-grain tablets.[3] The necessary number of tablets may be dropped into a clean tumbler of cold water and crushed to hasten their solution. The irrigator may then be filled or half filled with water, as hot as can be comfortably borne by the finger, and the glassful of solution poured into it. Great care should be taken that no undissolved particles of permanganate remain, as they will burn the urethra.

For convenience of calculation, the following sufficiently accurate table is offered:

	Potas. Permang.	Water.
1 to 12,000	1 two-grain tablet	to one quart.
1 to 6,000	2 two-grain tablets	to one quart.
1 to 4,000	3 two-grain tablets	to one quart.
1 to 3,000	4 two-grain tablets	to one quart.
1 to 2,000	6 two-grain tablets	to one quart.
1 to 1,000	6 two-grain tablets	to one pint.
1 to 500	12 two-grain tablets	to one pint.

Only in very rare cases will a quart of 1 to 1000, and only most exceptionally will a quart of 1 to 500 solution be required.

OTHER SOLUTIONS FOR IRRIGATION.

Silver nitrate is used in solutions of from 1 to 10,000 up to 1 to 500.

Mercuric bichlorid is employed in solutions of from 1 to 50,000 up to 1 to 5000.

Cupric sulphate is made use of in solutions of from 100 to 1000 up to 250 to 1000.

Largin, of the new silver preparations, is the richest—11 per cent.—in silver and seems thus far the most effective while gonococci are present in the urethra. The solutions used are from .25 to 1.5 per cent. Owing to the difficulty of correctly making these solutions, and the necessity for precision, it is best to have them made by a pharmacist in double the strength required. The patient can then dilute the solution with hot water to the quantity and temperature needed. Pezzoli,[4] who first advocated largin, recommended that it be retained at first for five, and later for fifteen, minutes. The difficulty of doing this and the use of a clamp for holding it in the urethra suffice to make this drug unpopular. If used in irrigation its ends are accomplished without this complication.

Mercurol, the newest gonococcocide, seems to promise even better results than the silver preparations. Its use in urethral irrigations may be safely begun with a .25 per cent. solution. The results obtained by irrigations of mecurol have been elsewhere published.[5]

As mentioned before, the selection of the drug to be employed in each case is governed by the conditions which prevail.

INTERVALS BETWEEN IRRIGATIONS.

The tables carefully worked out in "The Irrigation Treatment of Gonorrhea; its Local Complications and Sequelæ,"[6] show the precise intervals which should elapse between each irrigation in acute and chronic gonorrhea. It therefore seems unnecessary to repeat them here in detail. It will suffice to note that experience has shown no good results from irrigating with potassium permanganate, silver nitrate, mercuric bichlorid or cupric sulphate oftener than every twelve hours in the beginning of gonorrhea. Largin, however, does no harm if used three times daily, while mercurol irrigations sometimes prove efficacious when used every five hours during the day.

The technique of intravesical irrigation has been so fully discussed elsewhere by the writer that it need not be repeated in connection with the auto-irrigator. Only most exceptionally can a patient be entrusted to perform it, and even then with a degree of risk which few physicians care to incur. The majority of patients can, however, be taught to properly administer urethral irrigations to themselves, provided they can not, for any reason, visit the physician to have them done. The need of intravesical irrigation obliges even the most reluctant patient who has been taught the use of the auto-irrigator to visit his physician once on the third, fourth, ninth and tenth days. In addition to assuring the proper treatment on these days, the patient has the advantage of frequent examinations, during which the inception of any complication is observed and its consequences averted before they may become serious.

When intravesical and anterior irrigations are required on the same day, the former should be administered first, lest some of the stronger irrigating fluid left in the urethra be carried into the bladder, thus possibly producing cystitis.

With some men the compressor—muscle that holds back the urine—so easily relaxes that the fluid used in anterior irrigations enters the bladder, without any effort on their part. These persons should take their anterior irrigations sitting, with a hard towel knotted under the perineum—behind the testicles. Where this does not suffice to keep the fluid from entering the bladder, the patient can not be allowed to ever attempt to irrigate himself.

Occasionally a case is seen in which the discharge and all other evidences of disease disappear after one, two or three irrigations. For safety's sake the whole ten days' course of irrigations should be continued. And even then the patient must be warned not to deem himself cured until negative results have been obtained by the tests detailed elsewhere.

Should a patient apparently have recovered from gonorrhea, and then without any cause the discharge appears again, it is due to an infection of some of the organs in connection with the urethra. All practitioners should warn their patients that if the discharge should so appear while they are traveling they should seek advice as soon as possible from another physician if they are prevented at once from reaching their own medical adviser.

ACCESSORY PRECAUTIONS.

As the greater part of this paper is written for physicians whose experience with gonorrhea is somewhat limited, the principal precautions that a gonorrheal patient should observe are, for convenience, here placed together.

Food.—The diet should be nourishing and no changes made from the patient's habitual food. Articles difficult of digestion should be avoided, as should also late suppers.

Drinks.—All alcoholic drinks—whisky, brandy, beer, wine—should be positively forbidden. So also should all carbonated drinks, such as Vichy, Seltzer, soda-water, ginger ale, sarsaparilla, etc. An exception is made in reference to people who are habituated to stimulants with their food. Lest their ability to take the necessary nourishment be diminished, they may be allowed a glass or two of light claret at meals. Large quantities of water should be drunk, say a gobletful every two hours; or similar quantities of milk if patients prefer it.

---

[3] Patients have informed me that druggists occasionally offer for sale what they call "Valentine's tablets" for the treatment of gonorrhea. On investigation I have found these to be nothing but 2-grain permanganate of potassium tablets, distinguished only by an exorbitant price. Physicians should explain to patients that such abuse of the author's name is always unwarranted, and always springs from the cupidity and avarice of an unscrupulous dealer.

[4] Pezzoli, C.: Wiener Klin. Woch., Nos. 11 and 12, 1898.

[5] Phila. Med. Jour., May 12, 1900.

[6] Published by Wm. Wood & Co., New York, 1900.

Bathing.—The habitual daily bath need not be omitted because of gonorrhea. But to protect the eyes of the patient and those of other persons who may use the bathtub after him, he should, before bathing, cleanse the penis with absorbent cotton soaked in bichlorid, 1 to 6000, cover its head with cotton similarly soaked, and then draw a well-fitting condom over the entire organ.

Exercise.—While the patient should not indulge in vigorous exercise, he should walk in the open air enough to keep his general condition as good as possible. Bicycling, horseback riding or athletics in any form can not be allowed.

Suspensory bandage.—Every patient with gonorrhea should be advised to support the testicles continuously in a well-adapted suspensory bandage. It should have "back-straps" that pass between the thighs.

Stains from potassic permanganate.—Should patients, through awkwardness, stain their fingers with potassic permanganate, they will naturally desire to remove the stains. They may be instructed to use oxalic acid for this purpose, and duly warned to carefully wash the hands after its use.

AUTO-IRRIGATIONS IN PROSTATIC ENLARGEMENT.

It will at once occur to my colleagues that this apparatus must prove exceedingly useful in preventing the too frequent, sad results of self-catheterization as employed by old gentlemen with prostatic enlargement. It is perfectly true that many of these do not exercise even the precautions of ordinary cleanliness, despite which for a course of years they continue to live comfortably and are as well as is possible with such an ailment. But the many who die in consequence of infection are sufficient cause for deep regret to the physician, who was obliged to yield to their importunities to be allowed to relieve themselves.

In cases in which the feasibility of radical operative procedures is doubtful, or when the patient refuses to incur their risks, infection can be avoided by the following method of aseptic catheterization: Instruct the patient

1. To cleanse the mouth of the penis with absorbent cotton soaked in bichlorid, 1 to 6000.
2. To half fill the irrigator bag with warm 4 per cent. boric acid solution.
3. To wash out the urethra as directed above.
4. To insert the catheter.

After the bladder contents have passed off through the catheter:

5. The irrigator bag should be filled with a warm solution of boric acid, 4 per cent., silver nitrate, 1 to 2000 or 1 to 3000, or potassic permanganate, 1 to 6000—whatever solution the physician deems most desirable in the special case.
6. The nozzle of the irrigator is then to be inserted into the mouth of the catheter, the fluid is allowed to enter for a quarter of a minute, then the nozzle is removed to let the fluid escape from the catheter to cleanse it—this is repeated several times, until the fluid that comes from the catheter is quite clear.
7. Then the tip is reinserted into the mouth of the catheter and the liquid allowed to flow into the bladder until that viscus is comfortably filled—in some cases a smaller quantity is indicated.
8. The nozzle is then removed, and the bladder contents are allowed to escape.
9. Maneuvers 7 and 8 are repeated until the liquid flowing off is quite clear and transparent—in exceptional cases this can not be attained.
10. After the last emptying of the bladder as above, the liquid is allowed to flow into the bladder continuously for half a minute, then, without removing the tip from the catheter, the latter is slowly drawn out of the channel, which is washed by the fluid as it escapes during withdrawal of the catheter.

The above general directions must necessarily suffer modification according to the individual requirements of each case.

In conclusion I beg to submit: 1, that the auto-irrigator offers a safe and convenient means of anterior urethral irrigation in gonorrhea, when the patient can not visit his physician for the purpose; 2, that the auto-irrigator furnishes a convenient addition to the instrument bag for performing ante-operative and post-operative irrigation of the urethra and bladder; 3, that it is a most convenient apparatus for aseptic catheterism.

31 West Sixty-first Street.

TREATMENT OF PROSTATIC HYPERTROPHY.*

PARKER SYMS, M.D.
NEW YORK CITY.

Prostatic hypertrophy causes misery to a large proportion of men in advanced life, and results in such serious consequences that we must welcome every effort that is made to our means of curing or relieving its unfortunate victims. Fortunately much has been accomplished in this direction of late, and the author wishes to take this opportunity to present a new device that aids in the operation for radical cure.

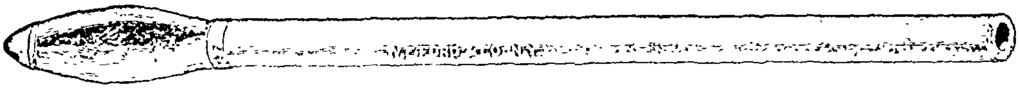
When the prostate gland becomes enlarged it sooner or later acts as an impediment to the emptying of the bladder. In some cases it causes but little obstruction; in others it prevents the passage of the urine till the bladder is filled and distended, when the urine may constantly overflow by dripping, which is a condition often mistaken for incontinence of urine; or the bladder may be partially emptied by the act of urination, but it can not expel the last part of its contents, which portion, known as the residual urine, remains in the bladder and becomes a source of trouble, as will be shown later. When the obstruction is established the bladder is called upon to exert an extra amount of force and the muscles become hypertrophied and the bladder-wall thickened. Later the muscles degenerate and, when the obstruction becomes more complete, the bladder becomes dilated and atonic. Finally, from the damming up of the urine, the ureters become distended and dilated and open up an avenue for infection of the pelvis of the kidneys. Infection of the residual urine and a consequent cystitis are produced after the obstruction has lasted a variable time, and it is then that the patient becomes one of the worst sufferers imaginable. Usually the cystitis will be brought about by infection through catheterization.

Until comparatively recently it was not known that hypertrophy of the prostate could be radically relieved; in fact, all attempts in that direction had failed or had been found to be so dangerous that they were abandoned as recognized procedures. So the only relief offered to the patient was that which could be given by the use of the catheter, and the degree of this varies immensely. Some who are leading the catheter life suffer merely from the annoyance and discomforts of having to use a catheter. Others are wretched from start to finish; because they become readily infected and are constantly passing from one attack of cystitis to another, perhaps spending their entire time, day and night, in futile attempts to empty the bladder, and suffering pain and torture which are frequently beyond endurance. In such cases much relief can be afforded by proper surgical care, but it is only after tedious treatment, and it is only with the prospect of the patient soon passing through another acute attack of the trouble.

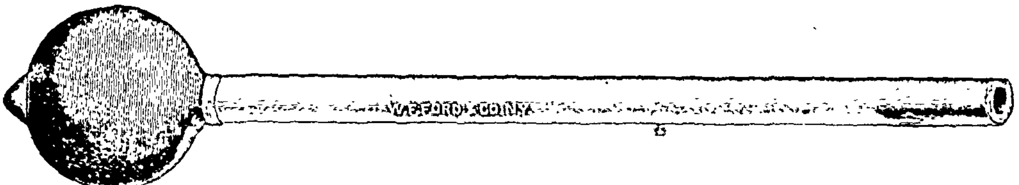
---

* Presented to the Section on Surgery and Anatomy, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

After prostatic hypertrophy is established nothing can afford permanent relief to the patient except some procedure which will remove the obstruction to the outflow of urine. Many useless procedures have been suggested and tried whose end was the cure of the hypertrophy of the prostate, but so far there remain but two methods which deserve favor in the minds of the profession. The first and most radical is some form of prostatectomy. The second is the prostatotomy performed by means of an electric cautery knife, known as the Bottini operation. This latter does not pretend to remove the hypertrophy of the prostate nor the gland itself. It is intended merely to effect a lowering of the urethral canal by dividing the prostatic portion in such manner that the bladder is able to empty itself voluntarily. The Bottini operation was devised over twenty years ago, by Enrico Bottini, of Pavia. At that time he published an account of the instrument used, and his results; the proceeding was rather extensively tried, but for some reason was abandoned. Recently it has been revived, and to-day it has many enthusiastic advocates who make great claims for it. The author has had no personal experience with this method of treatment, but it is advocated by such able men of late that he has fully determined to investigate it and try it for himself. It is an operation involving but little risk to the patient, and if it affords the relief claimed it is certainly of the greatest value. The most enthusiastic advocates of this method, however, do not claim that it will effect a cure or great improvement in all cases, and they concede that it yet remains for us to be able to distinguish just which class of cases are adapted to it and which are not. It still remains to be demonstrated how lasting or permanent the improvement may be in cases which have been benefited by the proceeding.



38 French Scale.



Dilated to 2½ Inches by Water.
Parker Syms' Bladder Retractor, for Perineal Prostatectomy.

A line of treatment in which the author has had experience is prostatectomy, and his results have been so gratifying that he has been led to feel that this operation is one of the greatest achievements of modern surgery. Unfortunately, at the present time the statistics, gathered from reported operations, have shown for this procedure a fatality so great as to condemn the operation if this death-rate must be conceded to be the normal or necessary one. The author believes that this death-rate is not owing to the fact that the operation itself is a very dangerous one, but to the fact that the patients, when operated on, have been unfit subjects for almost any surgical procedure. When prostatectomy can be performed safely and properly it results in an absolute cure of the patient, and it is the only method for which this may be said. The author has operated on patients who were unable to obtain relief by the catheter and by bladder washing, who suffered most excruciating agony night and day, who had a number of ounces of residual urine and the highest grade of cystitis. The result invariably was complete cure of the cystitis and complete restoration of the bladder function, so that the picture would be reversed, from that of a man who every fifteen minutes or half an hour passed a small quantity of bloody, infected urine, and whose bladder had several ounces of residuum, to one of a man who could hold his urine from six to eight hours and then absolutely empty his bladder with comfort, and whose bladder was free from any evidence of infection.

The above gratifying results are certainly all that can be asked for, and it only remains that we shall be able to bring them about with a reasonable degree of safety. It certainly is not doing justice to the patient, nor to the operation itself, if we undertake this procedure as a last resort. The author claims that the proper time to do prostatectomy is before great damage has been done to the bladder, urethra and kidneys; in other words, it should be performed as soon as it be determined that the habitual use of the catheter will be necessary. If that be the case one will be operating on a patient at his best instead of at his worst. The operation itself certainly is not a dangerous one, and in proper subjects the results should be very good and the mortality-rate low. The author would not advise operating on men who are physiologically very old, in other words, men whose arteries are markedly degenerated, whose circulation is poor, and who are decidedly feeble, but in the ordinary man of 60 or 65, whose bladder is still in good condition, the operation can probably be performed with safety.

In a paper entitled "Prostatectomy," which the author read before the New York Surgical Society, Nov. 9, 1898, he advocated the perineal prostatectomy of Alexander as the preferable method of those then in vogue, but he expressed his objections to the performance of the suprapubic cystotomy, and proposed that, instead, one should make a small opening in the abdomen above the bladder fold of the peritoneum, and through this wound he could push the prostate, bladder and all, down toward the perineum, so that, with the other hand, he could enucleate the lobes of the prostate.

ice writing that paper, he has operated through the ineum, but without making any wound above the bis. In one case he was able to crowd the prostate wn by manual pressure from above, because the abminal wall was thin and easily impressed. In other case he succeeded in reaching the prostate and ucleating its three lobes by means of a special reictor, which he devised and now presents. It consists a rubber tube made of the size and consistence of e ordinary perineal drainage-tube, on one end of which cemented a thin rubber bulb; the bulbous end is serted into the bladder through the membranous poron of the urethra, which has been opened, as after lexander; when the bulb is well within the bladder it dilated by being filled with sufficient water to expand into a bulb 2½ inches in diameter; then traction can made on the strong rubber tube sufficiently to bring e prostate into the perineal wound within reach of e finger, enabling the operator to perforate the capsule nd to remove the gland. The operator has used the straight median incision, not having found it necessary to use one of the transverse or curved incisions of Zuckerkandl, Dittel, or Rydygier, but in certain cases one of these incisions would have great advantage over the shorter ones of the median line. The point the author wishes to make is that prostatectomy can readily be done entirely through the perineum, and that it should not be combined with a suprapubic cystotomy. The author feels that the perineal drainage of the bladder is of importance when a cystitis is present, but that it is not a necessity otherwise, and if the patient presents himself for operation before cystitis has been established the operator should endeavor to remove the prostate without opening the urethra or the bladder.

In closing, the author wishes to urge upon his confrères the importance of the early recognition of obstructing prostatic hypertrophy, and also that they should submit these patients to a radical operation before the cystitis, prolonged pain, infection and fatigue have put them in a condition where they are unfit to undergo a surgical operation.

DISCUSSION ON PAPERS OF DRS. VALENTINE AND SYMS.

DR. C. C. THAYER, *Clifton Springs, N. Y.*—The paper on "Surgical Asepsis of Urethra and Bladder" is valuable, not only in showing how inflammatory conditions may be prevented in these organs, but cured. Cystitis is microbic in origin, and suppurative in character, the sine qua non being infection. The initiative and predisposing cause is structural change, and the provoking and perpetuating cause is inoculation with microörganisms, the vesical inflammation being instigated by bacterial infection and determined by circumstances. The urine is the medium of intelligent diagnosis of the presence as well as of the particular phase of cystitis; but considering the many pathological conditions that may affect the character of the urine after it passes the bladder the exact condition of the lining of the bladder can not be accurately diagnosed from urine passed in the normal way, or until all the parts affecting the urine after passing the bladder are free from pathological elements belonging to them.

As the pathology of cystitis may be embraced under impaired nutrition and structural change in the lining of the bladder, and bacteria of suppuration, the treatment is clearly indicated, but in reverse order, namely, to overcome the infection which produces the inflammation, the structural change which the inflammation produces and the imperfect nutrition which favors structural change; hence, local aseptic treatment is necessary in the treatment of cystitis. Milk or soft-food diet, saline laxatives as required, frequent hot sitz baths, hot poultices, hot salt bags or the Japanese stove over the bladder, and the patient kept in bed are important adjuncts in the treatment of acute cystitis. If the symptoms are not ameliorated in two or three days, the urethra should be disinfected, a soft aseptic catheter introduced, the urine drawn, the bladder thoroughly flushed with sterilized water 105 F., in which soda benzoate or Seiler's tablets, 2 grains to the ounce, is added, after which the bladder should be filled with some antiseptic solution. As the bladder has no anatomical, but a physiological, capacity, the quantity of water must be gauged according to the comfort of the patient, and the temperature about 105 F.

My method has been to use a one pint fountain syringe with a pipette nozzle, which can be readily attached or detached from the catheter after it has been introduced, so that the bladder may be flushed several times and germicides introduced before removing the catheter. Perhaps the bichlorid 1 in 3000 is most destructive to most of the bacteria, one to four ounces being introduced and then allowed to pass out. This is repeated twice daily for three days to destroy bacteria and spores, then leaving an interval of three days. As the bladder is improved, and the patient comforted in bad cases by frequent irrigations, other remedies and reconstructives may be employed, namely, two ounces or more of the strained infusion of verbascum, calendula or balsam of Peru, with two or three drams of formaldehyde solution to prevent the ammonical decomposition.

Chronic cystitis is often occasioned by prostatic hypertrophy so well set forth in the second paper. This condition is tedious and not hopeful in prognosis, except when normal anatomical relations can be restored. The two reasons for this are the mechanical obstruction to the flow of urine by the hypertrophied prostate, overcoming the normal action of the detrusor urinæ muscle, and the decomposition of the residual urine. Treatment for these cases should be as suggested in the treatment of acute cases and that applied to the hypertrophied prostate surgically, as well set forth in the paper, or by forcible dilatation of the urethra by warm bougies.

In acute attacks of the prostate, occluding the urethra, the condition becomes serious, because of the difficulty of introducing the catheter and emptying the bladder. Nearly a year ago, and after vain attempts by several to pass a catheter past a hypertrophied prostate, and after the parts were quite lacerated, a metallic catheter was finally introduced through the stricture, and fearing lest it could not be introduced again if removed, I kept it in place for sixteen days, through which the chronic cystitis was successfully treated, the urethra satisfactorily dilated, and since which the patient has had no further trouble.

DR. GEORGE CHISMORE, *San Francisco*—Dr. Valentine has presented a very ingenious instrument to prevent sepsis in washing out the bladder. Anything that will diminish the danger of irrigation must be accepted with pleasure. I am sure that much mischief often follows the introduction of germicidal solutions into the bladder. I do not believe any one can devise a germicide that will destroy injurious germs in the bladder and leave the organ unharmed. Of the last paper, in reference to the removal of the prostate gland through a median perineal incision, the method recommended seems a good one. Any means that will give permanent relief to the evils that arise from senile hypertrophy of the prostate gland deserves the greatest consideration at our hands.

On the whole, prostatic surgery has been disappointing; the future of this operation seems more hopeful. I have lately had the pleasure of witnessing a median perineal prostatectomy by Dr. George Goodfellow, after a method he has been using for several years with gratifying results. He places the patient on the back with the thighs very strongly flexed on the chest. This position gives the surgeon such a command of the prostate region that he can readily enucleate the entire gland through a very moderate incision.

DR. CARL BECK, *New York City*—The antiseptic, or rather aseptic, efforts of Dr. Valentine have my warm sympathy and I do not believe that too much antisepsis or asepsis can be practiced. Every introduction of an instrument into the urethra is virtually [illegible] tion, and should be preceded by the same care. If we do [illegible] operation on the outer surface of the body we do not conte[illegible] ourselves with pouring a little boric acid on it, but we are contented only after scrubbing with soap and water and subsequent application of alcohol and bichlorid of mercury or a similar antiseptic. Even then there is another surreptitious enemy of asepsis, intracutaneous bacteria, which should not be underrated. These can not be reached by any disinfecting process. They are set free as soon as there is an injury of the integument, and it is only by protecting the skin-margins of the wound with sterile compresses, after the skin is dissected that they can be kept in check. No precaution of this kind can be taken in the urethra, which moreover is a much more congenial resting-place for bacteria than the skin-surface of the body, the follicles offering microbic shelter, which can not be reached by intraurethral injection. If there is an injury, be it caused by a cutting instrument or by the friction of a catheter, not only bacteria of the intraurethral surface but also those sheltered by the follicles have a good opportunity to infect the adjacent tissues. This finds its simple clinical illustration in the fact that whenever blood shows after catheterization, there will be a chill, the instruments having opened an avenue for infection. Thorough prophylactic disinfection of the urethra is still a pious wish. This, however, should not encourage any sins of omission. As our active antiseptic drugs, like bichlorid of mercury, etc., can not display their valuable properties as fully in the urethra, we would better rely on a passive bacterial destroyer, like iodoform, which, while powerless where there is no injury, displays its unequaled properties in the presence of a lesion. Therefore, I advocate the prophylactic injection of 5 per cent. in glycerin before the introduction of an instrument in the urethra. If an abrasion is caused, the iodoform will come in contact with the wound-serum at its stadium nascendi. Iodin is set free, and during this chemical process bacteria are destroyed or their development at least is arrested.

Dr. F. W. Robbins, Detroit—I am surprised to hear the continual repetition of so many drugs as internal antiseptics. I have been interested in treating the urethra and bladder as recommended by Dr. Valentine for years, but I am not as enthusiastic as he has been. I am sure that irrigation of the urethra and bladder is of great importance. We find people among the laity who seem to think that they can irrigate the bladder just as well as we can, and they do not get the good results Dr. Valentine does. People feeling this way tend to throw the method of irrigation into disrepute, and any instrument which will become to the laity an easy one to use is going to still further increase the opposition to irrigation. The bag is very soft, easily broken and destroyed. I see no advantage over the ordinary fountain syringe with the exception of the arrangement at the nozzle. If the Doctor would throw aside all the rest of his instruments he will have a method which can be used in all cases where special treatment is necessary. Personally I consider urotropin to be the only internal urinary antiseptic of any value.

Dr. J. Rilus Eastman, Indianapolis—There can be no question that Dr. Valentine deserves great credit for having perpetuated and championed in America the useful principles of urethral irrigation as enunciated by Janet. Valentine has shown us that very often the catheter introduced for irrigation produces in mechanical irritation more trouble than is relieved by its flushing. Janet and Valentine emphasize four points in the potassium permanganate irrigation treatment of gonorrhea, namely that the solution should be injected hot, often copiously and under pressure. These are indisputably the cardinal points to be kept in mind. It is a question, however, whether all this can not be accomplished by a safer and simpler method than that of Dr. Valentine; whether the author's object can not be brought into execution as effectively and more conveniently with a large blunt-nosed metallic syringe provided with a protective shield. I believe that when the thumb pressing the piston becomes educated to the syringe, the pressure can be gauged as accurately and controlled as well as with the apparatus of Valentine. The large syringe is more easily sterilizable. When it is used the solution is taken from the top of the container by withdrawing the piston. The solution is therefore not apt to contain irritating crystals. When the permanganate solution is emptied into the jar of the Valentine irrigator the crystals, if any be present, precipitate at once to the bottom of the jar and are first to enter the urethra. It may be said that care will obviate the danger of introducing the crystals with the irrigator, but is it not after all a constant menace? The nozzle which Dr. Valentine has shown us this afternoon is too long and too pointed. It will certainly pass clear into the fossa navicularis of the average urethra and produce much irritation. It is made of soft porous rubber and will hardly be easily susceptible of perfect sterilization.

Dr. J. B. Bullitt, Louisville—The principles that Dr. Valentine stands for are certainly proper and right, but it seems to me that an apparatus such as he has exhibited to-day is unnecessary. Progress should always be toward the simple, rather than the complex, and, as one man has said, there certainly is no need of anything more for carrying out the procedure than an ordinary fountain syringe and a properly-shaped nozzle. The sheath is certainly of value, but I should say that the most important part of his apparatus is the little clip whereby the stream can be turned on or off. This is needed in many operating-rooms, and I shall adopt it. I do not think you can well gauge the pressure of a stream of water by the ordinary piston syringe, but you can gauge the amount of resistance, and that is all. I do not believe that this syringe is more easily cleansed than a fountain syringe. I do not know of any class of cases that tries the surgeon's patience, if not his skill, so much as an old man who has reached catheter life. Draining by suprapubic operations in some cases will work admirably, but many of the bladders become infected and contraction with thickening of the walls results.

Dr. F. D. Gray, Jersey City—I wish to assert my belief in the superiority of enucleation over the Bottini operation. I have not done the latter operation, but I see theoretical disadvantages in it. An operation, however, such as enucleation, which the average general surgeon like myself can do without having first witnessed it, simply having read the technique, and which he can perform with comparative ease and with a good result both as to recovery and as to the function of the bladder, is not an operation to be ignored. The invention of Dr. Syms is a good one, but I see some advantages in doing the old operation, comprising the suprapubic cystotomy. It is important to be able to have the tip of the finger inside the bladder on the prostate gland to make counter-pressure during the work of enucleation, and the device of Dr. Syms, while very ingenious, can not, in my opinion, take the place of the finger. I have also wondered why in place of suprapubic cystotomy it is not sufficient to force down the prostate with one or two fingers in the rectum, hooked over the prostate or against it, particularly while enucleation is being done with the other hand, thus avoiding opening of the bladder either above or below. In case the fingers can not reach sufficiently to produce counter-pressure in the rectum a proper modification of Syms' rectal speculum could certainly serve the purpose.

Dr. Ramon Guiteras, New York City—Washing out the urethra and bladder always improves their condition even if you use simple water or a saline solution, and the use of a mild saline solution enhances the value of the irrigation. Practice makes perfect in all cases. Dr. Valentine can irrigate patients much better than they can do it themselves, but if the Doctor is absent then the patient can be taught to irrigate himself sufficiently well to improve his condition. I do not think, however, that the patient should be allowed to irrigate when he has obstruction, as when the cystitis is dependent on a stricture, or an enlarged prostate. In employing this auto-irrigation method a certain amount might remain in the bladder and cause irritation. I do not believe there is any comparison between a piston syringe and a fountain syringe. A piston syringe can occasionally be employed, but in a majority of cases you can not be guided by the amount of pressure. A patient who is being irrigated always knows when his bladder is full and can tell you when he has sufficient fluid in the bladder to cause him discomfort; then the inflow should cease. All further distention may do harm and will certainly cause bladder strain.

As to the treatment of prostatic hypertrophy, it is still in its infancy, and when you come to consider the various methods of treatment of the day there are really only three or four: the catheter, enucleation and Bottini, with perhaps a palliative method with the formation of a permanent fistula. The question is when shall we do enucleation and when shall we do a Bottini? We should never do an enucleation in cases where there is a pyelonephritis, or very much damaged kidneys, or where there is a great amount of arterial disease. The class of cases on which to do an enucleation, as a general thing, can be determined by any one who has a good genito-urinary touch. He will find that the prostatic urethra is elongated and will be able to feel that bump or pillow, as you may call that projection of the middle lobe into the urethra. By rectal touch he can determine the size of the prostate, but very often simple manipulation of the finger is not sufficient in order to feel the prostate because the bladder prostate sometimes differs from the rectal prostate. A man may feel the prostate by the rectum and it may not seem to be large, but the middle lobe will extend up into the rectum and you will have a much larger prostate than you have any idea of. All these large prostates which feel like door-knobs when felt through the rectum are cases for enucleation. Lateral-lobe prostates are better enucleated by the perineal method, while if there is an enormous middle-lobe hypertrophy it is just as easy to enucleate by the suprapubic incision. In most prostatectomies there is a double incision. There is a certain class of prostatic hypertrophies where the Bottini operation is not very much needed, but it is indicated where there is a small middle-lobe enlargement causing sufficient impediment in the prostatic urethra to give rise to a large amount of residual urine. Such cases may be immensely improved by this operation, and it is not so dangerous as enucleation. In the case of a man who has a good genito-urinary touch and who selects his cases I do not think that the mortality from the Bottini operation should be more than 5 per cent., but in the hands of a novice who has simply read a description of the operation, there would be a mortality of not less than 15 per cent. In the most favorable cases enucleation would give a mortality of not less than 20 per cent. in the hands of the most experienced genito-urinary surgeon. There is no more difficult operation and it requires the greatest familiarity with the parts and the best surgical skill.

DR. F. C. VALENTINE, closing—Dr. Syms expresses preference for enucleation in confirmed prostatism. In this, I am convinced, the majority of surgeons agree, owing to the necessarily great hazards that still beset searing the prostate in the dark, as is done by the Bottini instrument. This operation, however, is likely to receive a new impetus, and become the less dangerous one, from the new incision-cystoscope recently devised by H. R. Wossidlo, of Berlin. By its means the obstruction can be seared under the guidance of the eye. As concerns my paper, I deem that our thanks are due Dr. Thayer for giving us, in his discussion, the benefit of his ripe experience. It is perfectly true that a number of colleagues have advocated the ordinary fountain syringes for urethral and intravesical irrigations. I need not call attention to the dangers to others of a household instrument being used for this purpose, nor the difficulties which its thick material imposes on the patient who for any reason can not be irrigated by his physician whenever necessary. Moreover the fountain syringe is of questionable sterilizability, while the little device I have shown can be boiled in its entirety and so rendered perfectly safe. In the treatment of enlarged prostate, when it is certainly impossible for the physician to relieve the patient's bladder and to wash it as often as necessary, the patient can be easily instructed to insert the soft conical nozzle of this auto-irrigator into the catheter, and to withdraw the nozzle as soon as he experiences a slight vesical tension. The fluid used for cleansing the bladder then escapes, as did the urine, through the catheter. With a little more instruction such patients can be taught, by the same means, to leave within the cleansed bladder, such a quantity of the antiseptic liquid as the physician may direct, and to further irrigate the urethra during the withdrawal of the catheter. I certainly agree, as must all others, who have had much to do with gonorrheal patients, that clap is entirely too dangerous a disease to allow any part of its treatment to be relegated to the patient. But there are circumstances in which the patient can not visit the physician with regularity. Moreover, there are men who discover their misfortune on the eve of a journey by rail or by sea and who must be helped to at least control the propagation of gonococci, as well as may be. The least intelligent of these patients needs but one lesson to perfectly accomplish anterior irrigation with the auto-irrigator. Such patients are more prone to avail themselves of their physician's advice, when its employment is rendered easy, as it can be with this device. Another consideration, and one of undeniable importance, is in the dimensions of the apparatus, which is so small that it can be concealed; this conserves the natural privacy which every patient desires to maintain regarding his infection. But I must emphasize the fact that I would never relegate the treatment of gonorrhea to a patient, unless when uncontrollable circumstances compel a makeshift.

All must quite agree that when there is no urethral discharge and when the urine is aseptic, and when careful asepsis is observed, the need of irrigating the urethra before and after instrumentation is not always imperative. I would add that this implies a degree of manual dexterity that all practitioners may not have acquired. We have all doubtless seen cases of urethral fever, with all its dangers, in patients who had been treated by others. Our obligation as teachers, it seems to me, embraces the advocacy of especially post-operative irrigation, which we know to be harmless and which, in the experience of those who employ it, has saved patients from urethral fever.

Dr. Chismore says that he does not appreciate how any remedies can destroy germs. I assume that he refers to those to whom infections of the lower genito-urinary apparatus is due. The Doctor voices the views and experience of all other learned men. But he will agree with me, when by a ready, easy and safe method of irrigation infection can be prevented, it is our duty to employ it, and that when an organ is infected it is equally our duty to strive to the mitigation of that infection by all means in our power.

Dr. Carl Beck reminds us of the bacteria which inhabit the normal urethra and which can be doubtless stirred into noxious activity by even the gentlest instrumentation. It is to Dr. Beck's credit that he suggested filling the urethra with sterilized oil containing 5 per cent. of iodoform, so that in the presence of those microscopic lesions which the gentlest instrumentation produces, the iodin which is then liberated exercises its bactericidal effect. The only modification that I would offer to this procedure, so in keeping with the behests of modern science, is the substitution of sterilized glycerin for the oil, because the glycerin being hydroscopic, permits effective irrigation, which would have but little, if any, effect on the urethra coated with oil. Let me repeat here that the results from irrigation can be best explained, in my opinion, by the artificial edema that it produces, rendering the mucosa an unfavorable culture-medium for bacterial propagation.

I regret that I must agree, in a measure, with Dr. Robbins in the danger of such an instrument as I advocate, becoming the property of the laity. But I must ask Dr. Robbins whether he would not prefer that his patients learned to appreciate the dangers of gonorrhea, by such means, rather than to continue to deem it trifling, and amenable to the little "P" syringe and the quack's or druggist's injections. It is just such scientists as himself who will be helped by the little device I have shown.

Dr. Eastman told us that the thumb could be educated to more intelligently gauge the pressure employed in copious urethral washings by means of a syringe, than by the stopcock of the irrigator. While dexterity may go very far in employing a syringe as a manometer, allowance will always have to be made for the differences in individual syringes, as well as in individual urethræ. With the auto-irrigator there is no element of chance; the hydrostatic pressure is graded at will and easily fitted to circumstances and conditions as they vary in each case and in the same case at different times.

DR. P. SYMS, closing—Some misunderstanding must have arisen in reference to the instrument mentioned, which is intended to be inserted into the bladder through an incision in the membranous urethra.

TREATMENT OF TUBERCULOSIS OF THE KNEE-JOINT.*

WISNER R. TOWNSEND, A.M., M.D.
NEW YORK CITY.

The treatment of tuberculosis of the knee-joint may be conveniently discussed under two heads: 1. Constitutional. 2. Local.

CONSTITUTIONAL TREATMENT.

The *constitutional treatment, as a rule, is much* neglected by most surgeons, although we admit that *no specific drug has been found that will cure or arrest* the progress of the disease in every case. Yet as it is not only often a severe drain on the general health, and chronic in nature, special attention should be paid to strengthening the individual and, by proper attention to diet and to his general health, placing him in the best possible condition to resist the attack.[1] As in pulmonary tuberculosis, much benefit is often derived from climatic treatment and from out-of-door life, so in bone tuberculosis the patient should be encouraged to be out of doors as much as possible, and, where the means permit, sent to such climates as have proved specially desirable in the treatment of such conditions. While some do best in high altitudes, others are better at lower elevations, but the crowded city, and the confining life of a hospital are not favorable to the best results. In addition, any organ of the body not in perfect condition should be looked after rather than all our efforts concentrated on the mechanical or surgical treatment of the knee-joint. Complete rest in bed rather than ambulatory treatment is indicated where the patient's joint is tender and where exercise seems to do harm rather than good.

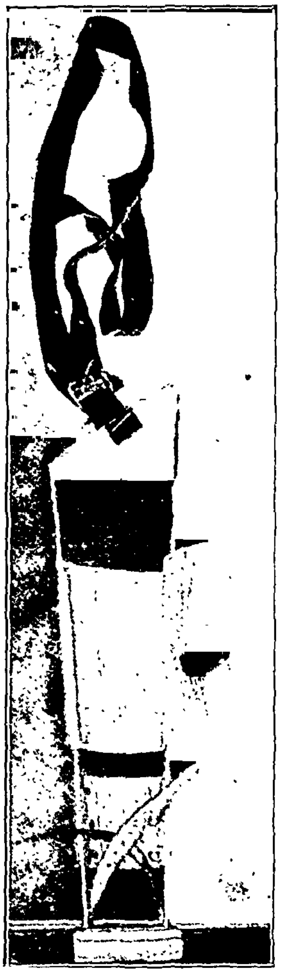
LOCAL TREATMENT.

Local treatment should have in view: 1, the proper protection of the articulation; 2, perfect rest of the joint; 3, the prevention or correction of deformity; 4, the removal of the tuberculous process; 5, the treatment of complications.

The proper protection of the articulation means not only that it should be saved from ordinary trauma, but that even the slight jar produced in walking should be avoided and every possible attention paid to keeping the diseased joint at perfect rest. This can not be accomplished if the patient is allowed to walk and bear the weight on the leg. Crutches are necessary in adults and should be used whenever possible in children. The sound limb should be raised by means of a high shoe or patten, so that the affected side may at no time touch the ground. The particular form of brace used may perhaps not be of great importance provided rest and protection are secured.

At the Hospital for Ruptured and Crippled, New York City, *the most convenient apparatus has been* found to be the Thomas knee-splint. It consists of two *bars of steel fastened at the upper end to a ring which* passes around the upper portion of the thigh, the inner *portion of the ring being just under the tuberosity of* the ischium, the patient thus sitting on it and transmitting the weight of that side of the body to the ground through the bars, one passing down the inner, the other on the outer side of the leg to a foot-piece 2 to 4 inches below the foot, covered with leather or rubber. A leather trough posterior to the limb prevents its slipping back and, by straps passing across the front, the entire leg is firmly held in the splint. Over the shoulders is placed a suspender fastened to the ring, which thus holds it up. If desired, adhesive straps can be fastened to the leg, and by means of straps on the foot-piece extension can be made on the lower leg and the knee-joint surfaces separated and slight deformities due to contraction of the hamstring muscles thus overcome.

To prevent deformity of the knee, plaster of paris, leather, silicate of soda or other materials may be used, but great care must be taken to see that they are made sufficiently long, *if we wish to accomplish anything.* As ordinarily applied deformity either occurs under the dressing or increases because the soft part of the thigh prevents the dressing being applied snugly. To firmly hold the knee and prevent flexion a spica bandage may be necessary; as it does not slip down and as the femur is controlled at both its upper and lower articulation, no deformity can occur. With the knowledge that flexion and other deformities usually occur, they should be prevented, but if they are already present steps must be taken to overcome them. Many methods are in use, the most common being by weight and pulley applied to the lower limb, by traction on the leg with adhesive strips and straps on the brace, the use of slight force and a retentive dressing, with or without a general anesthetic, local anesthetics being of no value, brisement forcé under anesthesia with or without tenotomy of the hamstrings, forcible correction by apparatus, osteoclasis, osteotomy, excision and amputation.



Thomas' Knee Brace.

---

* Presented to the Section on Surgery and Anatomy, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

[1] The use of creosote or guaiacol, so strongly recommended by some authorities, can certainly do no harm when properly administered.

The choice of one of the above methods suitable for a given case should not be a very difficult matter. During active disease no violence should be permitted, and even if anesthetics are employed, cutting operations are preferable to the use of great force manually applied, and a safe rule would be to exclude brisement forcé from our list. In all cases we must remember that once deformity has occurred it will remain, unless we correct it, and this should be done early, not only that the limb may be kept in proper position if, unfortunately, a cure is to result with a limitation of motion, but that the muscles, ligaments, etc., about the joint may not be unduly shortened or lengthened, as must occur if the joint is held in a faulty position. The use of an anesthetic and slight manual force with a retentive dressing is a rapid and safe method if properly applied. Extreme degrees of deformity may require osteoclasis or osteotomy if the leg is in knock-knee or bow-leg, and extreme flexion deformities may require excision or amputation.

When we come to consider the removal of the local tuberculosis, we find that many methods have been employed and abandoned, and that in the knee the use of tuberculin, iodoform emulsions, carbolic acid, chlorid of zinc, etc., have not been of great benefit, except in rare instances. The Biers method of passive congestion, much lauded some years ago, has gradually fallen into disuse, and we have to consider whether to do an arthrectomy, an excision or an amputation in a given case. We should, however, lay down the rule that the more perfect our mechanical treatment the less frequent will it be necessary to operate. Arthrectomy or arthrotomy is the most desirable operation in early life, where the soft parts about the joint are much involved. If properly done, all diseased tissue may be removed, both of the soft parts and the bone, and a useful limb, with good motion can be secured, but to be successful it must be done before the joint is destroyed. Excision should rarely be done in children, because it is not indicated in the mild cases and is not radical enough in the severe. The great objection to it, however, is that, by the removal of the diseased bone, the epiphysis is destroyed and the subsequent growth of the limb seriously impaired. The removal of half an inch at the age of 2 years may mean a shortening of 9 or 10 inches at the age of 18. After excision in children prothetic apparatus should be used to prevent subsequent deformities.[2] In adults excision is indicated in a large number of cases, and the mechanical treatment should not be kept up too long and is not followed by as good results as in early life. We might say: in childhood excise only in exceptional, in adult life in the majority of cases.

Amputation may be indicated for the correction of very severe deformities and in cases where the local process is so extensive that arthrotomy or excision are not sufficiently radical.

The complications requiring treatment are abscesses, sepsis and tubercular sinuses. The first two may seem to be similar conditions, but most pathologists recognize a difference. The cold abscess in the beginning is simply a chronic inflammatory condition typical of tuberculosis, but may at any time become septic. The treatment of the two conditions, however, should be the same—perfect and complete evacuation, thorough drainage and, where possible, the closure of the abscess and the obliteration of its cavity. When it is found to communicate with the bone, the local focus may also be removed at the same time. The treatment of septic knee-joints should be most thorough; if drainage is not perfect with the openings on either side, the joint should be thoroughly exposed and no "pocketing of pus" allowed. Excision in rare instances may be necessary, and where the local sepsis has caused grave constitutional symptoms amputation should be promptly resorted to.

The treatment of sinuses is a difficult problem: nearly every drug or chemical compound known to the profession has been tried, and each surgeon has his favorite prescription. Dissecting them out from the bottom, thoroughly cleansing and closing them, or the use of carbolic acid and alcohol, iodoform emulsions, balsam of Peru, hydrogen peroxid or silver nitrate solutions will generally effect a cure. In uncomplicated cases the general opinion is that complete protection should be given the articulation for a period of from two to three years, and in cases complicated by abscesses or deformity longer treatment will be necessary.

Attention to the general health, proper protection and rest to the joint, the intelligent prevention or correction of deformities, aided by proper surgical procedures, when indicated, will prove that tuberculosis of the knee-joint is a disease in which surgeons may accomplish much, and the results will fully justify the expenditure of our best thought and time.

In this paper statistics have been purposely omitted and an attempt made to simply call attention to the broad principles that should guide us in the treatment of this disease.

DISCUSSION.

DR. J. M. BARTON, Philadelphia—In the earlier stages of cold abscess, before any secondary infection has taken place, I prefer, instead of opening and draining, to entirely remove the broken-down tubercular material if this can be done, and then tightly close the cavity. When secondary infection has taken place, of course, drainage would have to be used.

DR. A. J. OCHSNER, Chicago—I agree with Dr. Townsend as regards the treatment of this condition and especially in reference to the first portion of his paper in which he speaks of the general treatment. In large cities there are certain neighborhoods from which we get our tubercular joints and we have such a place in Chicago which we call "Little Hell." If I succeed, in cases from this region, in removing or treating the joint in whatever manner may be indicated in the given case and obtain a good result, and the child returns to this same vicinity, it will certainly come back to the hospital in a year or two with the same joint involved or with tubercular glands of the neck or tuberculosis somewhere. Three miles from "Little Hell' is a section of the city called "Lake View," which is high and dry, where the soil is sandy and the houses are built of wood. There are no basements and all the houses have small yards. If during the time the child is at the hospital I can remove the family to Lake View so that the child can go there instead of back to "Little Hell" the child will gradually return to a healthy condition. Lake View is also occupied by the working classes the same as the other place, but the surroundings are much more favorable for this condition. I have succeeded in moving a number of the families from one of these places to the other, and I believe this portion of my treatment has done more good than a surgical operation. We must remember that these children belong to a nationality which depends very much on others for advice in these matters.

DR. J. B. BULLITT, Louisville—I think the paper is sound throughout, and I desire to call attention to the fact that the protective treatment in these cases has been more universally followed by good results than the operative treatment. Dr. Gibney took the trouble to follow up all the cases which were treated in the Hospital for Ruptured and Crippled in New

---

[2] The Prevention of Deformity after Excision of the Knee in Children, N. Y. Med. Jour., April 1, 1899.

York up to 1890. A great many of these cases had been treated by his predecessor, and the plan of treatment had been one of masterful inactivity and many of these cases have practically perfect functional joints. Many of the joints have good motion and are as good as other limbs. The comparison, therefore, as far as function is concerned, was very much in favor of the protective treatment. With the modern protection, such as Dr. Townsend employs, there would be a still greater comparison in favor of this method. That much good is to be accomplished along the line mentioned is unquestionable. The results which I spoke of as being obtained by Dr. Gibney were in cases treated in a large orthopedic hospital where the conditions were not nearly so good for recovery as they would be in private practice in smaller cities.

DR. T. J. SULLIVAN, Chicago—In Chicago, where we have many such cases, the great trouble all along has been with the general practitioner who does not recognize the conditions nor properly and promptly make the diagnosis, so that when the case comes for treatment a great amount of destruction has already taken place, and a great advantage has been lost. The diagnosis frequently made is that of rheumatism, but we may have a secondary mixed infection and great destructive processes can follow. If the profession can do anything in the way of prevention it is by an early diagnosis. Perhaps Dr. Mayo's operation, mentioned some time ago, of making an incision clear across the knee-joint and opening the joint thoroughly, may enable us to avoid amputation in many cases. Children are frequently surrounded by very bad hygienic conditions and tubercular processes go ahead with great rapidity, so that the most important point is the early diagnosis.

DR. W. TOWNSEND, closing—As to Dr. Barton's criticisms concerning the closing of the abscess before it becomes infected. I would refer to the portion of my paper dealing with that point.

THE EDUCATION OF THE SENSE OF TOUCH IN FEEBLE-MINDED CHILDREN AND ITS CONNECTION WITH MANUAL AND INDUSTRIAL TRAINING.*

FLETCHER BEACH, M.B., F.R.C.P.
Physician to the West End Hospital for Nervous Diseases, London; Formerly Medical Superintendent of Darenth Schools for Imbecile Children.
DARTFORD, ENGLAND.

Dr. Seguin long ago pointed out that the proper way to educate feeble-minded children was by education of the senses, and that the more thoroughly this education was conducted, the better would be the training which could be afterward given. On this occasion I intend to concern myself more especially with the sense of touch, only alluding to the sense of sight when it may be necessary to do so. Mr. Herbert Spencer has shown how by evolution and specialization the other senses, smell, hearing, sound and taste, could have sprung from touch, and how touch is a universal language into which the other senses which are special languages would have to be translated in order to be understood. Thus we know that the vibrations of ether which strike on the retina stimulate the fibers of the optic nerve, and these fibers, when excited, have the power of awakening the sensation of light in the brain. This is one variety of touch. Another variety is that connected with the auditory apparatus. It is well known that bodies which produce sound are themselves in a state of vibration, and this vibration is communicated to the air with which they are in contact and so throw that air into waves in the same way as a stick waved backward and forward in the water throws the water into waves. These aerial waves entering the ear impinge on the drum of the ear and set it vibrating. This vibration is, by means of delicate structures contained in the ear, communicated to the branches of the auditory nerve in the ear. These being excited produce in the brain the sensation of hearing. It is therefore clear that the sense of touch is a very important one.

But in order that the sense of touch should be well developed it is important that the nervous structures of the skin should be in a normal condition, and that common sensation, as it is called, should be developed to the full amount.

Now, sensation in feeble-minded children is much more dull than in ordinary children, and they do not suffer pain to the same extent. Instances have been known in which the extraction of a tooth seemed to cause little inconvenience and patients occasionally pull out their hair when annoyed. I had a little girl under my care at Darenth, and she at times gave way to violent passion, and would bang her head against a wall or bedstead if not prevented. Dr. Grabham says that he has more than once or twice seen a comparatively intelligent feeble-minded boy sit quietly in a chair while his toe-nail was removed, requiring no one to hold him, and uttering no exclamation, but looking on as if interested, and stating that the operation did not hurt him. He also mentions the case of a child who had severely burned his hand by holding it in a gas flame, and yet he took the first opportunity after recovery to endeavor to renew an experience which did not appear painful to him.

I think the case that impressed on me the idea that feeble-minded patients do not suffer pain to the same extent as sane patients was that of a woman whom I saw in the dining-hall at Darenth Schools. As she was sitting down to dinner I noticed that she looked pale, and made inquiries of the nurse if there was anything the matter with her. Not being satisfied, I asked her to walk upstairs to her bedroom above. On examining her, to my great astonishment, I found that she had fractured her fibula, and yet she was able to walk downstairs and upstairs again, and did not complain of pain. Another sign that sensation is more dull in these feeble-minded children than in ordinary children is that many of them are quite indifferent to cold or heat. Without manifesting the least sensation or apparent inconvenience they will in some cases remain, if allowed, exposed to the heat of the sun in summer and to extreme cold in winter. They have chilblains in winter, owing to their weak circulation, and in summer may get slight sunstroke, but they do not appear to notice either. The skin in chilblains, though attacked, does not give rise to perception, that is, the child does not perceive anything wrong. The sensation of touch exists, but sensation is dulled, either because the perceptive center is wanting, or because the peripheral organ, that is, the skin, can not be relied on to transmit a sensation.

From what has been stated, it is quite clear that common sensation is defective and that the sense of touch must be cultivated. This may be done by making the child grasp hard and soft objects, and by passing his hand over various substances, such as marble, velvet, cloth, silk, etc., so that he may learn to distinguish the different impressions produced by smooth and rough objects. So sensibility to heat and cold may be discriminated by putting the hands into hot and cold water, or by handling bottles or other objects filled with water of different degrees of warmth.

---

* Presented to the Section on Diseases of Children, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Having educated the sense of touch, we can pass on to the training of the hand, or manual training, as it is called. In ordinary kindergarten schools great attention is paid to the training of the hand, but previously to the time when this was first brought into use Seguin was at work training the hands of the feeble-minded, and his methods have to a great extent been incorporated with those which are now in use. If we notice a feeble-minded child who has had no education, we shall find there is a great want of co-ordinating power in the muscles, so that the hands with difficulty perform simple acts, such as picking up a pin or buttoning a coat. In the ordinary child this power is acquired early in life, but in feeble-minded children, especially if they have had no previous education, this power is not acquired until late, and if the education is stopped too soon, it is never acquired at all. Thus, I have seen boys and girls, even at the age of 15 years, unable to dress themselves because their manual training had been completely neglected. Parents have an idea that our only object is to teach their feeble-minded children to read, to write, to count, and to paint, etc., and the idea that manual training is required never enters their mind. No doubt this is due to the fact that ordinary children acquire this manual training almost instinctively, whereas feeble-minded children do not acquire it without being specially instructed in it. If you examine a hand of one of these children you will often find it soft and supple, but in directing the child to use the fingers you will see that the movements are badly directed, because the co-ordinating power which directs these movements is not properly developed. Now, how are we to develop this co-ordinating power? The answer is, by manual training. Of course in every case there must be some will power to put into use, for without a will there never can be anything executed. The training of the hand to useful occupation is simply a later stage of the cultivation of purposive movements aided by the progressive development of the senses and the intelligence. If you notice a baby, you will see a number of spontaneous movements, which are, however, quite purposeless, but as age and intelligence begin to dawn, these spontaneous movements are intuitively, or under the care of the mother, brought into coordination and by degrees are made use of for useful purposes. This is what is meant by purposive movements, that is to say, movements which have some purpose in view. In some low-class idiots you will notice quite purposeless, or automatic movements, as they are sometimes called, such as rocking the body to and fro, flicking the fingers before the eyes, and so on, and these movements have to be replaced by purposive movements. Again, you may observe children who suffer from spasmodic or choreiform movements. There are some children who suffer from athetosis, an affection producing constant slow, irregular movements, and in such cases it is necessary to produce a proper co-ordination of the muscular movements. A child suffering from this athetosis should be set to pick up and place in their proper cavities the marbles on a solitaire board. Afterward, what is called a peg-board will be found useful: it is simply a piece of wood with holes in it, in which metallic or wooden pegs have to be placed. The pegs have first to be grasped by the thumb and forefinger and then inserted into the holes in which they fit quite tightly. Then come exercises in threading beads and perforating picture cards, and the building bricks into various forms. All these exercises are exceedingly useful for children suffering from athetosis, as well as for the restless children who are often met with in this class. In all these exercises the hand is supplemented by the eye, and as a rule the hand and eye always work together. This is clearly recognized to the extent that there is a periodical published monthly called *Hand and Eye*.

Many of the exercises mentioned as useful for promoting co-ordination, such as building bricks, threading beads, perforating picture cards, etc., are useful in promoting manual training.

Size and form boards will also be found useful in cultivating accuracy in grasping objects. The size-board is a flat piece of wood in which are rounded cavities of various sizes, into which circular pieces of wood have to be placed, so that the small piece of wood goes into the small cavity and so on. The form-board is also a flat piece of wood with circular, triangular, square, oblong, etc., cavities, into which the corresponding pieces of wood of circular, triangular, square and oblong shape have to be placed. At first you will notice that the child will endeavor to put the square into the round hole, but as time goes on he will distinguish the varieties of shape and place the square into the square hole, the triangular into the triangular hole, etc.

Another method is to have a cushion covered with spots into which the child sticks pins; this will be found useful for training the hand in fine muscular movements.

Easy drawing lessons, painting and making pictures with colored chalks are also useful. Dressing lessons may be given with advantage, not only individually, but as a class exercise, in order to assist children to put on their clothes. Buttoning and unbuttoning clothes, lacing boots and tying bows or knots not only effect this, but ensure fine adjustments of the fingers, which is so necessary to be learned by the feeble-minded. In some cases it may be necessary to teach the use of the spoon and the knife and fork.

As regards industrial training, many of the kindergarten occupations will prove serviceable preliminaries to handicraft. Paper-weaving is an excellent preparation for sewing and darning, and the instrument which pricks perforated pictures will, in the hands of a skilful pupil, often lead to his employment in the shoemaker's shop; sloyd work, too, may in time lead on to carpentering. It must be remembered that these exercises do not merely train the fingers, but also through them the intelligence as well. Clay modeling, variegated paper mats and bead necklaces not only train the fingers, but excite a spirit of emulation which is useful as a stimulant to the feeble-minded child. There are many children who learn more with their hands than their head, and in these industrial training has an advantage over book-learning, such as reading and writing. Of course, the employment to which the child is put must depend to a great extent on his liking or disliking it. Some, for instance, will prefer carpentering, others gardening, and others cane-making or brush-making. Out-door is, of course, preferable to in-door work, but in this variable climate, especially in winter, it may be difficult to continue it, but where there is a farm this objection does not hold good, as the children or boys are under cover, and as they are generally fond of animals, they will be found to take great interest in the cows, pigs, fowls, etc., which are usually placed there.

For children who live in towns, these occupations can not of course be made use of, so that the country in this respect has a great advantage over the town. For those who live in towns, however, there are many kinds of work which will be found useful for the employment of manual training. Cane-weaving and basket-making are easily learned, and so are Macramé work; and wood-carving of a simple character may be even learned by advanced cases. Knitting, crochet and darning should of course be learned, as these occupations will come in very useful, not only for the institution, but for the home, if the child should improve sufficiently to be discharged. In the cases of the rich, there is a great range of employment open, but for those who are children of working men much can be done. Work on the farm or in the garden will be of use in the country, and, if in a town, cobbling, tailoring, basket-making and mat-making should be taught. Girls should be trained in domestic work and in the laundry and also in making garments.

I am aware of the somewhat fragmentary nature of these observations, but they have been put together in the course of a busy life. Such as they are, I hope they may be of use to the audience to whom they are addressed.

EUTHANASIA—A MEDICOLEGAL STUDY.

LOUIS J. ROSENBERG, LL.B., AND
N. E. ARONSTAM, M.D., PH.G.
DETROIT, MICH.

The last moments of our earthly career, the moments of transition from life to death, present a solemn and direful spectacle. To employ means to keep the dying individual a little longer on life's shore, or to hasten his "shuffling off this mortal coil," is a question which frequently confronts the physician. We are aware that death does not always come gently, "as light winds, wandering through groves of bloom, detach the delicate blossoms from the tree." Most men die from violence or disease; euthanasia is a rarity. Indeed, it is so rare that the afflictions of only a few organs or structures may bring about this kind of dissolution. We refer to organic cardiac diseases and cerebral apoplexy.

The term "euthanasia" has been variously defined, and is still a word of considerable controversy; so much so that "euphoria" was taken to be its synonym, and in a measure, perhaps, rightly so, as we shall see later. Euthanasia is originally derived from the Greek prefix *eu,* meaning well, and *thanatos,* death, or, in other words, "a painless death." This is the etymological signification of the word. There is also another meaning to it, to-wit: "a *means* for producing an easy death." It is with euthanasia, as expressed in the latter definition, that we shall deal in this paper.

The application of euthanasia is quite ancient. Egypt is, perhaps, its cradle. There it was extensively practiced among its priests, and to a certain extent among the military caste. To these chosen castes, stoicism was unknown; pain, degrading. The priests took upon themselves the solemn oath to alleviate pain whenever it existed, by any means whatsoever. Their medical armamentarium was deficient. Some of the important narcotics and anodynes were absolutely unknown to them. When remedial agents had proved inefficacious, and when death seemed inevitable, euthanasia was the only and last resort. Asia, especially the Orient, follows Egypt in this particular quite closely. The Bible tells us of the easy deaths of Abraham and Moses, namely, that the soul was kissed away by the breath of the Omnipotent. (See Rashi, Bible Commentator.) In fact, the ancient Hebrew considered an easy death to be an earthly reward from Heaven, to which only the righteous one could lay claim. Of the peaceful departure of Buddha, the Veda and Sanscrit furnish us with a beautiful picture. There it is stated, that on Buddha's command, the most venomous of serpents, the cobra, inserted its fangs in the locality of the forearm, and that Buddha thus died away in ecstasy. This and other methods of producing euthanasia are still in vogue in many parts of India. Rome and Greece offer us traditions of a similar nature. In these two countries the most prevalent method of producing euthanasia was to sever the radial artery. Another favorable mode was a goblet of hemlock. Even in modern times, the Mussulman, and, to some extent, the wily celestial, induce euthanasia by inhaling the fumes of the great somnifer, opium, and roll into everlasting dreams of enchanting houris or extensive rice fields.

What these semi-barbarians do unconsciously many civilized nations do as a result of ripe consideration and scientific decision. In this respect France ranks foremost. Whether those conclusions, however, are compatible with the highest principles of ethics, is the question to be discussed in the present paper.

Judge Simeon E. Baldwin, of New Haven, Conn., in the course of an address delivered before the American Science Association, of which he is president, made the following remarks:

"Of late years, it has become the pride of many of the medical profession to prolong such lives [meaning the lives of patients incurable] at any cost, discomfort and pain to the sufferer, or of suspense or exhaustion to his family. The patient has come to a point where he can not bear the thought of eating. The throat declines to swallow what the stomach is no longer able to digest. He craves nothing but to be let alone. A few hours, and Nature will come to his release. She is already, perhaps, fast throwing him into that happy unconsciousness of pain which we call lethargy. The vital forces have been spent. The mainspring is broken and the watch has run down. It can be made to tick feebly for a minute or two by shaking it hard enough; but cui bono? Only another mainspring can mend it. Only another soul, another world, can give value to this human life that is ready to flicker out because it is worn out. . . . Nature has kindly smoothed the sufferer's pillow by leading the way to that gradual exhaustion of the vital powers which follows the refusal of the stomach to receive or to digest food. To force nutriment into the system in such a case through other channels is simply to prolong a useless struggle at the cost of misery to the patient and to the profit of no one but the doctor and the nurse. In determining the nature of a disease, we look for the cause to the symptoms. Nature has so ordered it that symptoms are observed at that time of life when life is most worth saving. A lesion of one organ may then be expected to produce a reaction throughout the system. There is a general sympathy of the parts. On the other hand, in old age, the outward manifestations of an interior lesion seldom indicate that more than one organ is affected, and are often hardly noticeable at all. The patient does not know that he is a patient. There is no occasion that he should. The weakest part of his bodily mechanism has broken down. Why patch it up? Another is hardly less weak, and must soon succumb. Better for him and for his friends that his last days should be unclouded by the apprehension of coming death, and the change come to him quietly as a dream in sleep."

It is evident from what we have cited that Judge Baldwin holds that the physician's duty to save life is only applicable in cases where there is a life to be saved. Where "the mainspring is broken and the watch has run down" there is no use of repairing. Under such circumstances it is best for the patient himself, as well as for his friends, that his life should uninterruptedly pass. By no means would the Judge tolerate the patient to suffer. He also suggests that death "come to him quietly as a dream in sleep." In a word, he favors euthanasia, only in a limited sense, however. At no time during his entire address does he state that physicians should directly hasten death; though should the physician act on Mr. Baldwin's advice, he would really do so indirectly.

Prof. L. F. Barker, of the University of Illinois, at the conclusion of an address delivered before the Ontario Medical Association, Toronto, June 6, 1900, remarked: "If radical cure be impossible, he will not forget the palliative; if at last the exitus lethalis can not be prevented, he will at least see that the end is euthanasic."

The French Academy of Medicine, at one of its meetings, after listening to many cons and pros concerning euthanasia, conclusively asserted that its application is justifiable whenever death is extremely agonizing and only a question of hours. But it was Dr. Bach who advocated euthanasia—in the sense of being a means to produce death—determinately. In 1895, at the Medicolegal Congress, the learned Doctor said: "Physicians have the moral right to end life when the disease is incurable, painful and agonizing." In this country, however, we are not favorably inclined to the dicta expressed above.

To administer drugs with the knowledge that it will produce euthanasia would not only amount to an indictable crime at law, but it would also be regarded as an incongruity to the ethics of the medical profession and to public morals at large.

"Euphoria" is what the physicians in this country will sometimes apply. The term euphoria means the aptitude to bear pain. It also signifies "causing comfort." That is why euphoria is frequently used synonymously with euthanasia, and that is the utmost that our physicians here will accede to. In no case will they directly hasten death.

As a matter of law, it is well settled that euthanasia—in the sense of being a means of producing an easy death—is prohibited. It is an old legal principle that the taking of a life is only excused if it is so done to save a life. In cases of abortion, for instance, the fetus may be sacrificed, if it is necessary, for the purpose of saving the life of the mother. Of course, it may be argued, that a person can only be guilty of homicide if his conduct was the direct cause of death. Hence, if the patient was suffering from a mortal wound he would have died anyway; euthanasia only hastened his end. But such reasoning is fallacious, and not recognized in law. According to law, "causing death and hastening death are the same thing, for all men must die some time." This doctrine is well recognized, and was upheld in Com. vs. Fox, 7 Gray, 585; State vs. Costello, 62 Iowa, 404; State vs. Scates, 5 Jones (N. C.), 420.

In the case of People vs. Ah Fat, 48 Cal., 61, it was held that if one suffering with advanced pulmonary tuberculosis, of which patient would have succumbed within a month, and a person knowing the patient's condition, should intentionally drench him "with cold water, by reason of which death supervenes immediately, he is as much guilty of murder as though he had stabbed him with a knife."

In cases where the physician has no actual knowledge of the danger of his treatment, on account of his own ignorance, so much so that it will amount to gross and reckless carelessness, he is guilty of homicide. (See State vs. Center, 35 Ver., 378; Commonwealth vs. Pierce, 138 Mass., 165.) In connection with this, it should be remarked that if a physician administers a certain drug, fully believing that the drug so administered will not do harm, but that it will benefit his patient, and contrary to his anticipations, it kills him, the physician is not indictable; i. e., providing the physician exercised ordinary care and prudence. (See 6 Mass., 141.)

In England, also, it is well established that the physician is liable for careless conduct. (See Rex vs. Williamson, C & P., 635; Tessymond's case, 1 Lewin, 169; Ferguson's, 1 Lewin, 181; Rex vs. Long, 4 C. & P., 398; Rex vs. Senior, 1 Moody, 346; Regina vs. Whitehead, 3 C. & K., 202; Regina vs. Chamberlain, 10 Cox, C. C., 486.)

From the foregoing it is obvious that the inability of the physician to foresee the evil consequences of his treatment has no weight with the courts of England and America. The question is always, whether the court found "the evil consequences" obvious. And this responsibility of the physician is binding on him independent of the consent of the patient. (See Commonwealth vs. Collberg, 119 Mass., 350.)

Should a case occur where it would be imperative to administer the maximum dose of a remedy, with the intention of assuaging pain and suffering, and should the attending physician anticipate that such quantity is apt to produce simultaneously cessation of the vital functions, and thus anticipating, should he still run the risk and administer that dose, what would be his liability? The law in such cases implies malice. He would, therefore, be guilty of homicide. (See People vs. Sanchez, 24 Cal., 17; State vs. Wells, 61 Ia., 629; Tooney vs. State, 5 Tex., 163.)

Thus far we have shown the consensus of opinion of the medical profession, and the decisions of the courts. This, however, by no means solves the problem. Whether euthanasia shall be practiced or not still remains an open question.

We know that in many cases euthanasia would indeed be a godsend. Let us illustrate it by the following case which occurred in the practice of one of the leading physicians of this city: A man aged 70, German by nationality, received a paralytic stroke disabling him of voluntary locomotion. In consequence of this, he became confined to bed. Improvement set in very gradually. Contrary to the advice of the physician, he began to indulge in walking. He stumbled, fell and contracted an intracapsular fracture of the hip-joint. The same was reduced, but on account of his advanced age union did not take place. Chronic invalidism was his share. He could never leave his bed. Due to degenerative changes, decubitus set in, producing much distress and agonizing pain. In spite of good care, feeding and proper medication, he grew worse. The ulcer extended peripherally and into the deeper structures, laying bare the tuberosity of the ischium. The discharge was fetid and cadaverous, necessitating frequent dressings. He was an incessant menace to himself and his family. He lamented bitterly and implored the physician to induce death. Even the family could not endure the suffering of the old man, and corroborated his plea. To change the dressings meant disgust and malaise on the part of the members of the family and the physician. Half a grain of morphin was given hypodermically for the pain thrice daily, but without avail. Piecemeal, that man rotted away, a source of horror to himself and his surroundings. Such a case is but one of the instances that occur not infrequently in the physician's practice. Would it not be an act of mercy to practice anesthesia to its fullest extent and allow death to "come to him quietly, as a dream in sleep?" On the other hand, should the portals to the application of euthanasia be open, there is hard telling at what stage they would close.

Human beings are presumptuous. Make no restrictions and matters will run riot. Society, in order to maintain and protect itself, can not rely on the judgment of certain individuals. The law, therefore, laid down hard and fast rules, which every one, without exception, must obey. Human beings are weak; temptations are great. Should law be silenced on this point? Some physicians might, under the pretense of doing a merciful act, really commit a deed of felony. Let us illustrate. An old man, very wealthy, is suffering from an acute attack of peritonitis. He has an unlawful child to whom he thinks to bequeath his estate. He also has a nephew who is nursing him, and who is aware of that fact. This nephew is very anxious to possess himself of this old man's estate. Something must be done to prevent the old man from carrying out his intentions. The attending physician is a poor man. The nephew offers him a thousand dollars to apply euthanasia. The physician yields to the temptation. He hastens the old man's ascent to Heaven, and a double wrong is thus committed, to-wit: a life is taken and a rightful heir deprived. It is thus seen that the permission of the application of euthanasia would not infrequently be a paving of the way to injustice and crime. What, then, should we do?

Having considered both sides of the issue, our conviction is that, after all, it is far better for the welfare of society to let a few suffer, and not run the risk of creating crime and criminals. It appears to us that there is ample reason to dread that the practice of euthanasia would, in the long run, cause more harm than good. That is why the law, laboring as it always does for the good of the majority, has logically prohibited it. The working principle of jurisprudence is still the celebrated adage of the great utilitarian, Jeremiah Benton, the greatest happiness to the greatest number.

In no case, therefore, should the physician intentionally or directly cause death. "Causa causæ est causa causati" should be his warning. In other words, whenever the treatment of the physician is the direct cause, he should be considered as having created the cause; hence, he should be held responsible for its effects.

The physician is always under a great responsibility. At no time can he ever exercise too much caution. Due to the variety of circumstances, and the complexity of human nature, no ironclad rules can be laid down. But as a general proposition, it might be stated that he should at all times do his utmost to alleviate pain, and make the pangs of death as void of agony as possible. By doing so he will have complied with the highest standard of ethics, and will earn the gratitude of humanity.

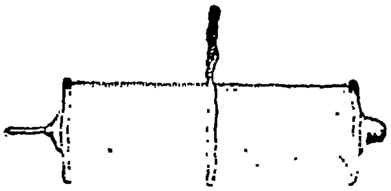
Large Child.

Dr. J. Pfeiffer reports in the *Orvosi Hetilop*, No. 34, what he considers the largest child born in good health and spontaneously. As quoted in the *Bull Méd.*, the child weighed 6600 gm., or about 14.1 pounds. It was 55.5 cm. in length, and the head measured 37 cm. in circumference. The placenta weighed 2150 gm. and the cord was 53 cm. long.

REMOVAL OF A PIECE OF STEEL FROM THE GLOBE BY ELECTROMAGNET.

WALTER B. JOHNSON, M.D.
PATERSON, N. J.

James Andrews, 35 years of age, was presented to me by Dr. William S. Colefax, of Pompton, N. J. March 24, 1900. The patient had received an injury of the eye. While nicking bars with a steel chisel, a chip flew from the bar and struck him in the left eye. The foreign body punctured the globe at the upper third of the cornea, inflicting an oblique wound which extended entirely across the cornea in the superonasal quadrant from limbus to limbus. It passed into the globe through the iris and lens and into the vitreous chamber. The iris was prolapsed and the globe apparently filled with blood. The eye was cocainized and approached with the small end of the magnet devised by the writer; the piece of steel located and as it was engaged by the point of the magnet it was gradually withdrawn, the resistance being very slight. The prolapsed iris was then snipped off and the edges of the wound coapted.



The removed steel was crescent-shaped, 3/8 inch in length, over 1/8 in width and 1/16 in thickness.

The eyes were bandaged and the patient sent to the Paterson General Hospital. He remained in the hospital four weeks; during the first two weeks the eyes were kept bandaged. He made a slow recovery, but never had any pain. During the next two weeks the eye was protected by London-smoke glasses. The only symptom which annoyed him was lachrymation on exposure to the light. There was considerable injection, which persisted. The pupil was distended and the lens cataractous. On May 19, there is very little redness of the eyeball remaining; there is no pain; the patient's health is good. He has been working for the past week; he still has some lachrymation in the left eye in the morning. The tension of the eyeball is normal; the patient can see shadows; the cataractous lens prevents ophthalmoscopic inspection. The appearances indicate the preservation of the eyeball and possible subsequent operative procedure for visual effect.

Medical Testimonials to New Remedies.—This was one of the chief questions discussed at the German Congress of Physicians and Naturalists held at Aix-le-Chapelle in September. Prof. His stated in his address that the creation of a central official laboratory for the testing of new remedies was an urgent necessity. No physician should write a testimonial in favor of a new remedy unless he has exceptional opportunities for testing it in hospitals or clinics. It should only be addressed to the profession and no one should be allowed to use it for advertising purposes in the daily press nor for general distribution. Physicians whose inventions are commercially exploited are responsible for the manner in which the advertising is conducted. Kobert insisted that before a remedy can even be advertised in the medical press it should be subjected to thorough theoretical tests in the chemical, bacteriologic, pharmacologic and physiologic laboratories and then tested on animals.

THE USE OF INTRA-ABDOMINAL CULTURES IN COLLODION SACS IN THE STUDY OF BACTERIA.

The method of research recently introduced by the successful cultivation, by Nocard, of organisms enclosed in collodion sacs and placed in the abdominal cavity of living animals, has been used by Vincent[1] in the study of the pathogenic adaptability of saprophytic bacteria. He found that by this method harmless varieties of saprophytes, such as B. megaterium and the potato bacillus, could be changed into virulent organisms capable of producing toxins and causing general infection. As pointed out by Nocard, the walls of the collodion sacs permit of a ready change in the composition of the fluid within them, thus preventing auto-intoxication of the bacteria and at the same time the body fluids enter gradually and furnish sufficient food for the germs, which thus become exposed to the influences of growth under the new conditions.

The bacillus megaterium became virulent after four passages, of six or seven days each, through the bodies of animals into which the bacilli were introduced in collodion sacs partly filled with bouillon; intermediate cultures were made on ordinary media between each passage. It now killed mice, guinea-pigs, and rabbits, by producing a general hemorrhagic septicemia. At the same time changes in its growth form were observed. Grown under ordinary conditions the newly acquired virulence was lost again in three months. While virulent, vaccination, with the production of immunity, could be made.

The potato bacillus acquired pronounced virulence after four to seven passages. Spores heated to 100 F. and recultivated did not lose their virulence, but transmitted it to their descendants. The bacillus became pathogenic by virtue of production of toxin and by causing general infection. In this case also the appearances of the cultures were changed.

These interesting experiments demonstrate the plasticity of microbes; it appears possible to subject saprophytic organisms to a progressive education, as it were, adaptation to parasitic life being acquired by cultivation in living media. As would be expected, the saprophytes thus treated have a tendency to recover their hereditary characteristics, but the fact remains that they have been shown to be able to elaborate toxic diastatic products and destroy cells while the bacteria multiply in the ruins. It appears that the distinction between saprophytic and pathogenic microbes is rather an artificial one.

Centani attempted to cultivate the virus of rabies in collodion sacs, but without success. Nocard,[2] however, apparently succeeded in securing pure cultures of the microbe of contagious pleuro-pneumonia of cattle by inoculating some of the material from the lesion into collodion sacs filled with bouillon; he then inserted them into the abdominal cavity of guinea-pigs and other animals. After a time the fluid became turbid and, although the smear preparations did not reveal any microorganisms of such size as to be recognizable with our present powers of magnification, yet the inoculation into cattle of the contents of the sacs, incubated in the animal organism, produced the disease in typical form. Nocard concludes that the organism is so small that we are not now able to see it.

As pointed out by Trudeau,[3] the collodion-sac method of experimentation offers broad fields for the study of the influence upon the germs, their virulence and products, of the growth under such conditions, and for the study of the effect of freshly and continuously elaborated toxins on the living organism while the latter is protected from the direct pathogenic consequences of the spread of the microbe throughout the system at large. The method also seems to open new possibilities in attempts at successful production of artificial immunity and the obtaining of antitoxic substances for the treatment of diseases.

CAN PYOGENIC BACTERIA PENETRATE THE NORMAL GASTRO-INTESTINAL MUCOUS MEMBRANE?

This question has been variously answered by different investigators who have studied it experimentally and otherwise. Bacteria have been found in the chyle of normal animals by some investigators, while others have not been able to demonstrate bacteria in the chyle. Similar contradictory statements are made in regard to the presence of bacteria in the fluid in the hernial sacs. The passage of bacteria through the intestinal walls is held by some to be cause of peritonitis in intestinal paralysis, but even this is denied by others. Kocher was the first to call attention to the gastrointestinal canal as an entrance point of pyogenic infection, e. g., in osteomyelitis. His experiments, made as long ago as 1879, are hardly convincing in the light of accumulated knowledge, and later experiments of others have given contradictory results—Karlinski obtaining positive results from feeding experiments, Alapy and Neisser negative results. This contradiction is probably explainable, at least in part, by the use in some of the experiments of material of but little virulence, and on the other hand by infection from the pharynx, which Lexer has shown recently may follow the introduction of a few drops of culture of virulent streptococci into the throat.

---

[1] Ann. de l'Institut Pasteur, 1898, xii, 785-798.

[2] Ibid., pp. 561-568.

[3] Bull. of Johns Hopkins Hospital, 1899, x, 121.

Bail[1] has studied the question again. The experiments were made on rabbits. Five to six cubic centimeters of a highly virulent streptococcus suspension in bouillon were introduced into the stomach of rabbits by means of a soft-rubber tube, great care being exercised to prevent the escape of streptococci into the pharynx. Of 40 animals 7 died from a general streptococcus infection. By means of culture experiments and of microscopic sections it was found that the cocci made their way through the intact mucous membrane of the small intestine and into the blood-vessels of the mesentery. Ribbert and Bizzozzero found bacteria in the normal lymph-follicles in the vermiform appendix of rabbits, and Bail also found bacilli and cocci in these follicles but also streptococci in the walls of the small intestine —where bacteria are normally absent—in 5 of the 7 rabbits that died. Presumably a local superficial enteritis induced by the streptococci prepared the way for their entrance. Bail concludes that intensely virulent streptococci may penetrate the normal intestinal wall and cause a general infection. These results are opposed to those of Buchbinder, who introduced bacteria into the intestinal canal, portions of which he then compressed by means of rubber rings; but it seems according to Bail that the bacteria used were not shown to be highly virulent, and furthermore that the methods used for demonstrating the bacteria in the intestinal walls are open to criticism. Bail's results indicate that virulent streptococci may invade the organism from the lumen of the normal intestine.

The only possible objection to this conclusion would be that infection after all took its point of departure in some other region, such as the pharynx, and that the streptococci found in the intestinal walls were there by virtue of a hematogenous transportation—a sort of elimination—and not as the result of entrance from the lumen. This objection, however, seems somewhat far fetched.

BLASTOMYCETIC DERMATITIS.

The number of cases of this form of cutaneous infection is increasing constantly. Up to this time it seems that typical blastomycetic dermatitis has been recognized and studied by Americans solely. There are now about twenty recorded cases in which the diagnosis is satisfactorily established by the study of the microscopic character of the lesions and the characteristic, budding, doubly-contoured organisms usually present in the little abscesses that form such a prominent feature of the clinical as well as the anatomical picture. And yet it is to be remembered that absolute demonstration of the etiological rôle of the organisms is still wanting. No one has produced blastomycetic dermatitis by experimental inoculation of human beings with pure cultures, and in the ordinary laboratory animals the convincing cutaneous lesions do not follow local infection. But the clinical picture, the histopathology, and the presence of the organisms, which are often easily isolated, at other times with great difficulty or not at all, have left no doubt as to the entity of the disease in the minds of those who have had occasion to actually study it.

Dyer,[1] of New Orleans, describes an instance involving the hands, face and leg of a woman of the better class; he compares the disease with yaws, a widespread cutaneous affection of unknown nature of the West Indies, but without reaching any definite conclusions as to the identity or difference of blastomycetic dermatitis and yaws. Montgomery and Ricketts[2] describe three new cases of blastomycetic infection of the skin, giving full histopathological and mycological details. One case is especially interesting, because the lesion, situated on the lip, much resembled squamous-celled carcinoma. It developed in a man who worked in grain elevators and who had handled grain affected with "dry-rot"—fungous disease. Hyde and Ricketts[3] also describe fully two new instances. In this article is brought out well the peculiar action of potassic iodid in this disease. Given in drop doses of a saturated solution and increased up to the limit of toleration, the iodid in many cases produces a marked improvement of the lesions, but as yet no complete cure has been secured. Here is seen a means of great aid in differentiating blastomycetic dermatitis from cutaneous syphilis on one hand and verrucous tuberculosis on the other. There is no good evidence at all that any of the cases of blastomycetic dermatitis so far observed were in reality examples of other diseases, e. g., carcinoma or syphilis with accidental implantation of blastomycetes. The increased knowledge of blastomycetic dermatitis will lead to the accumulation of observations and as previously emphasized in these columns[4] there is good reason to believe that many instances of this affection have been, and probably are being, mistaken for carcinoma and tuberculosis.

LAY COMMENT ON PATIENT'S INGRATITUDE.

A physician was recently stamped to death in Oklahoma by an ex-patient from whom he was trying to collect a bill for medical attendance. As a lay journal remarks, this appears "to be only a little more exaggerated example of the ingratitude which is manifested every day by a world in which billions of people are very quick to call physicians and very slow to pay them." It is refreshing to note this comment, indicating as it does a correct appreciation of facts in a quarter where it is not always looked for.

NEWSPAPER ENTERPRISE.

The Seattle (Wash.) *Times* of December 26, announces the opening of the Pan-American Medical Congress on that date. The news comes to it by special dispatch; the number of physicians in attendance is given at about 1000, of whom 300 were Cubans, and a large number of Mexican delegates had arrived on a Mexican warship. Few, it says, were in attendance from South America, the distance being too great for any large representation. As an example of newspaper enterprise of a certain kind this special dispatch is rather interesting.

NEW YORK STATE JOURNAL OF MEDICINE.

Number 1, Volume I, of this new journal is before us. It is published monthly by the New York State Medical Association and takes the place of the annual volume of transactions. The journal consists of twenty-four large double-column pages of reading matter, with eight advertising pages. It makes a good appearance and the committee in charge is to be congratulated on its efforts. This makes the third state body to publish a monthly journal in place of an annual volume, the other two being the Medical Society of the State of Pennsylvania and the Illinois State Medical Society. In each of these states the enterprise is giving satisfaction. It is certainly better to have a monthly journal go to each member than to have an annual volume and this to be placed on the shelf and soon covered with dust. Such a monthly journal gives an opportunity for the members of the medical profession of the state to exchange views on various topics of interest. We note that the new journal opens its pages to advertisers; this is sensible. There is no reason why respectable advertising should not be admitted to a medical journal, and we believe that it is common sense and business-like to accept such. Legitimate advertising is a benefit to the physician, as well as to those who supply him with the many things he needs in his work.

THE SAN FRANCISCO PRESS AND THE QUARANTINE OFFICIALS.

A portion of the San Francisco press has continually and consistently demanded the removal of the quarantine officer of that port, Dr. Kinyoun, because he has not, in the performance of his duty, met their wishes in denying or suppressing facts in regard to plague cases. They have even gone so far as to want him dismissed from the Marine-Hospital Service altogether, though for present purposes his removal to another sphere of action would be most welcome. The latest utterances, however, go farther and charge the head of the bureau with malfeasance in office in not mentioning the cases occurring as "reported as bubonic plague but the diagnosis disputed by the medical profession of San Francisco." The paper that contains the above, charges that the chief of the Marine-Hospital Bureau has deliberately falsified an official record, and suggests a Congressional inquiry. It is questionable whether the results of such a measure itself would be perfectly satisfactory; it might only extend the list of those whose acts and opinions are so offensive to a portion at least of the San Francisco press and public. If that city escapes a serious visitation of the plague, as it is hoped and trusted it may, it will not be due to the hysterical organs like those quoted and to the worried commercial interests backing them, but to the health and quarantine officials who are the subjects of their abuse.

MICHIGAN BOARD OF REGISTRATION AND LOW-GRADE MEDICAL COLLEGES.

The Michigan Board of Registration is making a praiseworthy effort to render efficient a rather imperfect medical-practice act. The Michigan law accepts diplomas from recognized colleges as a qualification for practice, but leaves the recognition to the Board, which, using its authorized discretion has thus far "recognized" some thirty odd institutions out of the two hundred, more or less, in the country. This discrimination is not an arbitrary one, but is based upon personal knowledge derived from inspection of these institutions. The committee of the board to which this duty was assigned, in its recent report, says in regard to some of the medical colleges that have come under its purview: "We regret to say that the printed announcements and catalogues of some of the schools do not represent the facts of the case as shown by investigation. A medical college on paper seems to be one thing and its genuine conditions and requirements as applied to students decidedly another." This is the official statement of a fact well known to every one in the profession and even a stricter scrutiny than that of the Michigan Board would not be amiss. If, however, its methods were universally or even generally adopted it would be greatly to the benefit of the standing of American medicine.

THE BELLEVUE HOSPITAL SCANDAL.

The recent scandal in Bellevue Hospital where certain male nurses were held to the grand jury by the coroner's findings for the killing of an insane alcoholic patient, illustrates a fact that is not always fully appreciated by the medical profession or the public. It is that ordinary nurses' training alone is insufficient to make anyone fitted for the care of the insane, especially the violent cases, a duty that requires special natural as well as acquired qualifications entirely different from those demanded of any ordinary nurse. In view of the general outcry of late years for trained nurses in hospitals for the insane, this fact is important; what may be called the essential moral qualifications of an ideal asylum attendant are not essential in the trained nurse, who is a much more easily manufactured product. This difficulty of obtaining ideal attendants is the most troublesome problem in asylum management, and not infrequently the cause of trouble and scandals. The discipline and morale, however, of a well-conducted asylum are such that fewer abuses occur than might reasonably be feared. Similar discipline is not readily applicable in a general hospital and might easily be lacking in an insane ward attached to it, especially if the ordinary training of nurses is depended on to qualify its attendants. The moral of the recent event in Bellevue is not "abolish the male nurse," as a New York paper puts it, but that trained attendants, not mere trained nurses, are required in a ward for the insane.

THE MEDICAL DEPARTMENT OF THE ARMY.

In this issue there appears a communication from the President of THE AMERICAN MEDICAL ASSOCIATION in regard to the pending bill for reorganization of the army in so far as it involves the medical department.

Dr. Reed shows how the proposed change in the original bill will affect the standing of the medical corps and through it the welfare of the army. It is a fact, but one only beginning to be occasionally appreciated and quickly forgotten again, that the medical department is the most important one in the army in time of war; it is practically the first line of defense and a most indispensable adjunct in offensive operations. In modern war disease is the worst enemy to be met, and it is only exceptionally that it is not responsible for the greatest mortality and combatant inefficiency. An insufficient, untrained or demoralized medical corps means uncontrolled disease and possible disaster, in any case a positive increase of inefficiency of the army as a fighting machine. We had ample illustration of this fact in our late war with Spain, where a trained medical force adapted to an army of 25,000 was called on to do duty for an army of ten times that size, the deficiency of medical force being made up by civil surgeons untrained in military needs. The British experience in South Africa is similar, and both furnish ample proof of the need of well-organized and duly-recognized medical corps. Dr. Reed points out clearly this need and how the proposed legislation will affect it. It remains for the medical profession to use its influence in behalf of the army surgeons and to secure for them proper recognition and treatment in the reorganization.

BLUE GLASS REDIVIVUS.

Many of our readers will recall the blue-glass fad of the late 70's which had a brief career. While it lasted many popular articles appeared upon it, and a book was written which is still occasionally to be seen in second-hand book stalls and elsewhere. While some individual experimentation was undertaken at the time the subject was not considered seriously by the medical profession. It scarcely made any impression on medical literature of the day, at least we can recall no articles of note; it was generally dropped as a popular craze and quickly passed out of fashion. Judging from present developments in phototherapy in which the violet end of the spectrum is mainly used, it may be that there was a neglected germ of truth in the craze after all. We knew nothing then of the Roentgen or the Becquerel rays, nor do we yet know all their possibilities. Now, however, a Russian physician, A. V. Minin,[1] reports remarkable therapeutic effects from the use of electric light passed through blue glass in arresting pain, in some forms of which, intercostal neuralgia for example, there is, he says, nothing like it "for effectiveness and rapidity of action." Its influence, also, in hastening the absorption of blood or effusion is likewise remarkable as he claims, and a number of cases are reported in which these and other advantageous effects were observed. Nothing in this is attributed by the author to other agencies than the blue light, though the question naturally arises whether the influence of suggestion was not in play. With the results reported, however, the experiments are worthy of a test, especially since nothing more than an ordinary 16-candle light from a 100-volt current, passed through blue glass, is required. The exposures varied in number and length in different cases, but were usually ten or fifteen minutes in duration and repeated as required, according to the case. It is hard to see how the applications can do any harm and if there is anything in it, which can not be absolutely denied *a priori*, it is worth a trial.

BACTERIAL TRANSMUTATION.

At a recent meeting of the Société de Biologie, Paris, Dr. Caldas, a Brazilian bacteriologist, reported experiments on the colon bacillus of the rat. By cultivating the organism with a certain mold derived from rice, *Aspergillus orizæ*, and passing it from rat to rat, he finally obtained a bacillus closely resembling the typical plague germ, in great numbers from the glands, spleen, stomach and intestines of the infected animals, which produced, when injected into rats, similar clinical symptoms and was always rapidly fatal. The biologic characters of this organism throughout were the same as those of Kitasato's bacillus pestis and he has no doubt as to their equivalence. He claims, moreover, to have succeeded in rendering a horse immune by venous injections of at first very diluted cultures of the germ, followed by more virulent ones, and with this horse's serum has been able to save rats that had previously been inoculated with the virulent cultures. He gives it as his opinion that the plague in its origin is a colon bacillosis of rats caused by the ingestion of rice containing a mold, *Aspergillus orizæ*, and that the colon bacillus by successive passages from rat to rat takes on the characters of the plague bacillus. Dr. Caldas' experiments do not appear as yet to have attracted much attention, but they are certainly suggestive. Our methods in the study of bacteria are not yet perfect and their taxonomic distinctions are far from being yet fully established. It may be difficult or even impossible to fully determine all the specific characters of these minute organisms, but until we do we can not be altogether positive as to their possible varieties and transformations. The identity of the Sanarelli bacillus of yellow fever is a case in point, and it may be mentioned in this connection also that Caldas claims this germ to be likewise a modification of the bacillus coli, the special virulence of which is due to the presence of a mold.

THE BACTERIAL SELF-PURIFICATION OF STREAMS.

Streams may purify themselves in two ways: of the chemical constituents of sewage and of sewage bacteria. The latter mode of self-purification is discussed by Jordan[1] on the basis of observations made during a study of the water of the Illinois river in connection with the newly constructed drainage canal connecting the Chicago river with the Desplaines river. This—a stupendous piece of sanitary engineering—was recently completed at an expenditure of about $35,000,000, and it conducts the sewage of Chicago into the Desplaines and Illinois rivers and finally into the Mississippi. In order to determine the condition of the water of the Illinois river a series of chemical and bacterial analyses of the water of this river and its tributaries was undertaken and carried on regularly during a period of about eight months. Throughout this period about 85 to 90 per cent. of the total sewage of Chicago passed into the

---

[1] Wratch. Dec. 1 (Nov. 18, old style), 1900.

[1] Jour. Exp. Med., 1900, v, 271-314. See abstract No. 29, p. 138, The Journal A. M. A.

Illinois river. Among other results it was found that at a certain point in the Illinois river—between Morris and Ottawa—a change occurred that might properly be regarded as self-purification, because during a stretch of twenty-four miles the river was nearly freed from the mass of sewage bacteria with which it was originally laden, the bacterial content being not greatly in excess of that of the local tributary streams. The cause of this disappearance of sewage bacteria is of interest. Mechanical agitation and aëration, dilution, the action of sunlight, the influence of the plankton, sedimentation and exhaustion of food-supply are discussed in the light of the facts at hand bearing on this particular case. Sedimentation and diminution of food-supply are settled on as the most important factors in the process of self-purification. At the point mentioned the conditions are very favorable for sedimentation, and the chemical analyses show also a marked decrease of albuminous substances, probably through bacterial agency, because there is accumulation at the bottom of foul black mud. Decomposition of large quantities of albuminous substance is first followed by great bacterial multiplication and then "speedy and extreme mortality of bacteria." Bacterial self-purification of streams may be attributed mainly to insufficient or unsuitable food-supply.

THE RELATIONS BETWEEN EPILEPSY AND ACUTE INFECTIOUS DISEASES.

It is a matter of common observation that the occurrence of the seizures in an epileptic is inhibited by acute intercurrent, febrile disease, although, on the other hand, it is equally recognized that, in children especially, eclamptic attacks are frequently observed with the onset of acute illnesses. It will not be maintained that the inhibitory influence in the one instance is more than temporary, while, on the other hand, it seems not impossible that both the frequency and the severity of the seizures in a case of epilepsy may be greater after than before the intercurrent disease, and occasionally acute disease appears to be the starting-point of the epilepsy in a predisposed individual. In harmony with the views expressed, is the experience of Clark and Sharp,[1] who report a series of cases of measles and erysipelas in epileptics in which the convulsive disorder was in no instance favorably modified for any great length of time, but, on the contrary, the progress of the disease was, in a few instances, accelerated by the intercurrent disease, and in one the epileptic status was induced, while in those cases in which the epilepsy appeared to be favorably modified the temporary improvement was slight and of short duration. A notion has prevailed in the past, and its influence has not yet entirely disappeared, that inasmuch as all individuals are likely to suffer from the exanthemata at some time in life they had better be exposed in childhood to mild attacks, but it has been shown that not a few remain immune, while at times the anticipated mild attack proved directly or indirectly disastrous. In view, therefore, of the failure of acute disease to exert a permanently favorable influence on epilepsy, and the possibility that such disease may excite the convulsive disorder or aggravate it if already present, it is the part of wisdom to avoid all risk of the infective diseases on the part of epileptics as well as on that of others. It may be set up as an axiom that no form of disease—with the possible exception of vaccinia—can be safely induced for prophylactic or curative purposes.

Medical News.

CALIFORNIA.

Dr. Charles D. Lockwood, Chicago, has moved to Pasadena and has opened an office at Los Angeles.

Dr. Frank H. Payne, Berkeley, was thrown from his buggy on December 27, and sustained a fracture of the thigh.

Dr. J. Ellis Rodney, Chico, who was convicted of perjury, sentenced to serve twelve years in the penitentiary, and who appealed to the supreme court, must serve his time, as the court affirmed the decision.

A hospital, equipped with all modern appliances, will be erected in Ventura by Dr. Cephas L. Bard and his brother, United States Senator Thomas R. Bard, in memory of their mother, Elizabeth Bard. The building will cost about $15,000, and when completed will be presented to the city.

DISTRICT OF COLUMBIA.

The site for the new Municipal Hospital, Washington, which comprises thirty-three acres, has been purchased for $65,000 by the commissioners.

Dr. Walter Reed, surgeon U. S. A., has been detailed as the representative of the medical department of the army at the Pan-American Medical Congress at Havana.

Alterations in the laws of the District are suggested by the District Medical Society to better protect the people of the District against disclosure of confidential information necessarily imparted to their physicians in order to receive proper medical treatment, and to render the general treatment of the office of coroner complete, harmonious and compatible with modern ideas.

ILLINOIS.

Charleston physicians have organized a club for mutual benefit and protection, with Dr. Lemuel L. Silverthorn, president, and Dr. Joseph A. Perkins, secretary.

Dr. Frank Parsons Norbury, who for the past four years has had charge of the medical department of Oak Lawn Sanatorium, Jacksonville, has resigned. Dr. Norbury will soon open under his own control and management, at Jacksonville, an institution for the private care and treatment of diseases of the brain and nervous system.

The commissioners of the Asylum for the Incurable Insane, at Bartonville, near Peoria, recommend in their annual report appropriations aggregating $669,000 from the legislature at its coming session. Of this, $200,000 is to be used for completing the work now under way, $225,000 for the erection of ten more cottages, and $139,000 for other additions to the institution.

Chicago.

By the will of the late Charles Higgins, St. Luke's Hospital will receive a bequest of $10,000.

During the last week 11 new cases of smallpox have been seen by the Health Department officials, in 8 distinct locations. There are now 15 smallpox patients at the Isolation Hospital.

During 1900 the patients of Cook County Hospital numbered 17,429, or 10 per cent. more than in 1899, with a mortality of 1287, or 7.38 per cent. The cost of maintaining the hospital was $268,825.

Dr. W. F. Arnold, U. S. N., of the local naval recruiting depot, has gone to New York to take examination for promotion. Medical Inspector Ezra Z. Derr, Portsmouth, N. H., is attending to Dr. Arnold's duties during his absence.

The Detention Hospital examined 1727 patients during 1900, 770 of whom were sent to the hospital at Dunning, 113 to Elgin, 179 to Kankakee, 346 were discharged, 18 had escaped from the asylum, and 13 died at the hospital.

The health department claims Chicago as pre-eminently the city of good health, and substantiates its claim by statistics. The death-rate per 1000 per annum in New York City was 21; in Greater New York, 20.57; in Brooklyn, 20.11; in Philadelphia, 19.86, and in Chicago, 14.56.

The health commissioner, in his recent report concerning smallpox, says that vaccination, repeated until it will no longer "take," is an absolute protection against smallpox, and nothing else is; and that the modern practice of vaccination, with sterilized vaccin lymph, under simple precautions of cleanliness, is positively harmless.

---

[1] Medical News, Dec. 1, 1900, p. 853.

A sharp rise in mortality marked the closing days of 1900. For the week ended December 29, 554 deaths were reported, 74 more than for the week previous and 100 more than in the corresponding week of 1899. There were 122 deaths from pneumonia, 9 from influenza, which is seriously complicating many other maladies; 47 from consumption, and 34 from violence.

On January 7, a society was organized by the faculty of Rush Medical College and will be known as the Medical Society of Rush Medical College. The secretary is Dr. J. B. Herrick, the presiding officer to be selected each evening. The executive committee consists of Drs. Frank Billings, L. Hektoen, J. Clarence Webster, L. F. Barker and the secretary. Meetings will be held monthly.

INDIANA.

The new quarantine hospital at Indianapolis was opened January 7. The building and equipment cost about $15,000.

Lomax Hall is to be the name of the $25,000 addition to the Medical College of Indiana, in honor of Dr. Lomax, of Marion, who donated his estate to the college ten years ago.

The Eastern Indiana Hospital for the Insane at Richmond asks from the legislature an appropriation of $301,000 for the next two years, $62,000 of which is to be used for the erection of two cottages.

IOWA.

Drs. L. W. Littig, of Iowa City, William Jepson, of Sioux City and N. C. Morse, of Eldora, have been appointed by Governor Shaw, as commissioners to represent the state at the Pan-American Congress at Havana.

The office of Dr. E. H. King, Muscatine, was recently burglarized and an emergency grip taken, containing a roll of surgical instruments, Kelly cushion, operating robes, trays, etc. The following night Dr. Olliver's office was entered and swept bare of instruments. Any parties offering second-hand, or other instruments for sale cheap should be regarded with suspicion.

KENTUCKY.

Dr. John L. Evans, Louisville, is critically ill with abscess of the lungs at Spring Hill, Ala.

The residence of Dr. William Bowman, Toleboro, late consul at Tien-Tsin, China, and state representative and senator, was burned December 12.

The suit for damages of $45,000 for criminal assault, filed December 19 against Dr. William Cheatham, has been dismissed. It was apparently an attempt to obtain hush-money from a reputable physician.

The quarantine against Greenup County, which was put in force December 23, was raised two days later, the action of the State Board of Health having roused the delinquent fiscal court to action. On Christmas day it held an extraordinary session and adopted a resolution to pay all legitimate bills for physicians' services, nurses, guards, etc., and telegraphed its decision to the State Board of Health, which thereupon raised the quarantine.

MARYLAND.

Dr. Grafton M. Bosley, Towson, one of the oldest physicians in the state, is seriously ill and has been removed to the Church Home and Infirmary, Baltimore.

Dr. Thomas C. Bussey, Texas, has been appointed physician to the almshouse and Dr. Richard C. Massenburg, Towson, physician to the jail of Baltimore County.

The third annual report of the Peninsula General Hospital, Salisbury, shows that during the year 110 patients were received for treatment, 70 of whom were free patients, and 5 of whom died.

Dr. W. S. Richardson, Williamsport, was assaulted in the Traver Hotel, Downsville, by the proprietor for an alleged insult to his wife, December 24. The Doctor's nose was broken, other injuries inflicted and his condition is critical.

The annex to the Western Maryland Hospital at Cumberland was opened December 28. The expense of this annex was met by the appropriation made last winter of $4000 by the legislature. It consists of a wide corridor connecting it with the main buildings, a large operating room, a sterilizing room, a bathroom, an elevator and four recovery rooms. The operating room is 18x20 feet, is lighted by six windows and by a large skylight. This is the only hospital in Western Maryland and draws from the neighboring parts of Maryland, West Virginia and Pennsylvania.

Baltimore.

Health Commissioner Bosley says that a complete sewerage system and infectious diseases hospital are absolute and urgent necessities for the health of this city, and he will use every effort to secure both. The mayor is backing him heartily.

Dr. Alfred R. Dohme has been appointed lecturer on pharmacy at the Johns Hopkins Medical School. Dr. Dohme is an A.B. of the Johns Hopkins University, and after his graduation went to Germany and there graduated as Doctor of Philosophy.

A board, consisting of Col. John M. T. Finney, chief surgeon, 1st Brigade; Major William H. Crim, surgeon, 5th Infantry, and Major S. S. Ullrich, surgeon, 4th Infantry, met at brigade headquarters December 28 to establish a standard of medical examination for recruits for the organized militia, as required by section 14a, militia laws, acts of 1900. The standard of examination will be modeled after that of the United States army.

The following officers were elected in the national societies recently meeting here: American Psychological Association: Prof. Josiah Royce, president; Dr. Livingston Farrand, secretary. Society for Plant Morphology and Physiology: Dr. Edward F. Smith, president; Profs. F. C. Newcombe and L. M. Underwood, vice-presidents; Prof. W. F. Young, secretary and treasurer. American Morphological Society: Prof. J. S. Kingsley, president; Prof. E. A. Andrews, vice-president; Prof. T. H. Montgomery, Jr., secretary. American Association of Bacteriologists: Prof. William H. Welch, president; Prof. E. O. Jorden, vice-president; Prof. H. W. Conn, secretary and treasurer.

MINNESOTA.

Daily inspection of the Minneapolis public schools is assured, as 75 physicians have volunteered their services to the board of education for this work. From these the requisite number will be appointed.

A St. Paul undertaker has been arraigned in the police court charged with presenting a death certificate to the board of health which had not been signed by the attending physician, Dr. James S. Gilfillan. The certificate bore the doctor's signature, but he claimed to have no knowledge of the matter.

The Winona city council, on December 22, accepted the resignation of Dr. Donald B. Pritchard as a member of the local board of health, and elected Dr. Darwin A. Stewart to fill the unexpired term. A week later Dr. Stewart's resignation was accepted and Dr. Pritchard elected to fill a vacancy in the board.

The new quarantine hospital at Minneapolis, which has just been opened, is said to be the most complete institution of its kind west of New York. It has accommodation for 48 patients, half in wards and half in private rooms, in addition to the building used for the reception of patients and the use of the hospital staff. The hospital has cost about $16,000.

Health Officer Franklin Staples writes: In your Minnesota news of last week's Journal, you notice an epidemic of smallpox at Winona. For the next number of The Journal the revision of the notice should be as follows: Disease decidedly on the decrease. Number of cases reduced is nearly 50 per cent. The disease is of a very mild type, a kind of anomalous smallpox, such as has been prevalent lately in many places and in different parts of the country. Instead of "a few deaths" as erroneously reported, the correct statement is that no deaths have occurred from this cause.

MISSOURI.

Charleston has passed an ordinance prohibiting the sale of cocain and similar drugs.

Free vaccination to all who apply has been volunteered by 12 Kansas City physicians.

Three Chinese "doctors" in Kansas City, Wong Sang, Lee Coon Hung and Wong Hay Shine, have been arrested for practicing medicine without a license. The prosecutions were instituted by the State Board of Health.

The city council of Louisiana, on account of the prevalence of smallpox, has issued a proclamation prohibiting public gatherings of all kinds and closing the public schools. The health officer, Dr. T. Guy Hetherlin, has resigned on account of the lack of heed paid to his warnings and advice, and Dr. Ira Miller, of Ashburn, has been appointed his successor.

"The World's Health Institute and College of Medicine, Surgery and Science" has been incorporated at St. Louis by a homeopathic physician, two laymen and a physician whose name is not to be found in the directory, with a capital of $50,000, to conduct a health institute, a college of medicine, surgery and science, and incidentally to buy, sell and rent real estate.

The St. Joseph Medical Society held a fin de siecle meeting and banquet December 31. About 50 guests were present. Dr. Jacob Geiger presided as toastmaster; Dr. Thomas H. Doyle spoke on "St. Joseph's Pioneers in Medicine"; Dr. Pierre L. Leonard, on "Medicine of the Future"; Dr. John M. Bell reviewed the history of the St. Joseph Medical Society, and Dr. Charles Wood Fassett responded to the toast, "The Medical Press."

MONTANA.

Post-Surgeon Gibson and his wife were injured while driving near Fort Harrison, Helena, December 24. Dr. Gibson was badly bruised and had his shoulder dislocated, and Mrs. Gibson had a dislocation of the elbow.

Dr. Daniel L. Carmichael, Helena, has renewed his contract as physician of Lewis and Clarke County at a salary of $1800 per annum. In consideration of this he agrees to attend the sick at the poor farm, county jail, all sick poor within two miles of the city and all smallpox patients.

The Commissioners of Silver Bow County have adopted a sure way of forfeiting the respect and losing the co-operation of the physicians of the county. In reply to the protest of the county medical association against the lax methods employed in dealing with smallpox, which is epidemic there, the commissioners admit that the sanitary conditions are bad, but charge the physicians with being partially responsible for the prevalence of the disease, in that they have ignored the health laws and treated smallpox patients in secret. About the same time that this reply was being formulated, a request was made to the board to put an infected house in a thickly populated district under quarantine, but the board refused to do so.

NEW MEXICO.

Coal miners are bringing influence to bear to locate the hospital for miners at Gallup. The hospital tax on miners, which began October 1, will amount to $1000 per month.

Dr. Percy G. Cornish, surgeon-in-charge of the Santa Fe Pacific railroad hospital at Albuquerque for the last four years, has resigned and has been succeeded by his assistant, Dr. John M. Elder, whose place will be filled by Dr. Raymond Russ, of Los Angeles, Cal.

The Sanatorium for consumptive seamen at Fort Stanton has been a success thus far. In the first eighteen months of its existence 92 patients were admitted from the various marine hospitals, 12 of whom were discharged as recovered, and 15 as improved. Eleven patients died.

NEW YORK.

The Supervisors of Albany County have elected Drs. Arthur Sautter and Mark S. Lavy, Albany, Edward M. Bell, Cohoes, and Martin S. Reid, Coeymans, coroner's physicians at a salary of $600 a year.

On October 1, 1900, there were 22,088 inmates in the various state hospitals, an increase of 653 over 1899. The average increase has been about the same for the past five or six years. The expenditure per capita was $165.38.

The physicians of Schenectady objected so strenuously to the action of the General Electric Company in securing a physician from Albany to vaccinate the 5000 employees of the company, that the Albany physician asked to be relieved, and a Schenectady physician was employed.

Health Officer Goler, of Rochester, announces that for the past two months there has been, on an average, one new case of rabies in dogs reported each day, and the situation is becoming alarming. Autopsies and laboratory experiments have proved beyond all doubt that it is true rabies.

Cortland is the center of an epidemic of typhoid fever. The city hospital is full of patients and the management is compelled to turn applicants away. Many factories and business houses are crippled because of the illness of the employees. The cause of the epidemic has not yet been determined.

The Chairman of the Senate Committee on Finance held a conference in Buffalo recently with Senator Henry W. Hill and Dr. John H. Pryor, concerning the completion of the state consumption hospital in the Adirondacks. The result of the conference was that the committee will add the item of $200,000 necessary to complete the building, to the annual appropriation bill. The trustees of the hospital have selected a second site for the institution at Raybrook, between Saranac Lake and Lake Placid, and not far from the Lake Clear site, which was first selected.

Governor Odell, in his first message to the state legislature, calls attention to the state board of health, which consists of three commissioners appointed by the governor. The duties are such that one competent man, giving his entire time thereto, he thinks, might easily perform them, provided that the supervision of tuberculosis and glanders in cattle were transferred to the department of agriculture, where it properly belongs, thereby removing the necessity for a large office force at corresponding expense. This change is suggested with a recommendation of affirmation by the legislature.

Buffalo.

Dr. Frederick H. Mills, of this city, has been appointed acting assistant-surgeon in the army, and has been ordered to the Philippines.

Of the thirty physicians in New York whose names appear on the list of those eligible for positions in state institutions, nine reside in Buffalo.

Influenza is prevalent in Buffalo. The disease is characterized by a high range of temperature, and is principally of the respiratory type. Many pupils are prostrated and between fifty and sixty school teachers are unable to attend to their duties. In some instances entire families have been attacked.

New York City.

It is estimated that a million persons have been vaccinated in Greater New York since an epidemic of smallpox threatened.

By the will of the late Henry Villard, Dobbs' Ferry Hospital Association receives a bequest of $50,000, and New York Infirmary for Women and Children, $5000.

The health board has recommended to Commissioner of Charities Keller that a new ward be established at Randall's Island solely for the accommodation of children with contagious diseases.

The report of the committee on the library of the New York Academy of Medicine shows that on Nov. 30, 1900, the library contained 89,000 volumes. During the year, 3649 volumes were added; 971 books and 832 journals were issued to 194 readers. There were registered 11,520 readers during the year.

The extremely high mortality among the infant charges of the city has engaged the attention of the commissioner. The mortality among the children on Randall's Island for 1899 was 45.05 per cent., and for the first nine months of 1900, 46.67 per cent.

A few cases of smallpox continue to develop in widely separated sections of the city. So far, there have been 84 cases in the Borough of Manhattan, 2 in Brooklyn, and 5 in the Bronx, and of this number 3 have terminated fatally. There are now 61 cases isolated on North Brother Island.

OHIO.

Youngstown is to have a new hospital, to cost from $150,000 to $200,000, the entire cost being defrayed by Myron C. Wick and his family.

Dr. Oliver W. Lindsay, Columbus, has resigned as secretary of the Health Department, and taken up his work as coroner of Franklin county.

The Cincinnati Academy of Medicine has presented to Congress a protest against any reduction in the Medical Department of the army, below the other staff corps.

Dr. Albert E. Warren, Youngstown, is reported critically ill at Hot Springs, Ark., the result of an infected wound received during an operation several months before.

The charges against five women and one man in Cincinnati, of unlawfully practicing medicine, have been withdrawn, as the accused have complied with the law, registered with the state board of examination, and have been granted permission to practice.

PENNSYLVANIA.

Lancaster is to have medical inspection of the public-school children.

The trustees of the State Hospital for the Insane at Norristown met January 4, cast 21 ballots without result, for a successor to Dr. Tabor and adjourned till January 18.

An epidemic of typhoid fever prevails at North Bend, near Renovo, where 11 cases have been found. It was discovered that these persons had used water from a spring near which there had been a case of typhoid fever.

Philadelphia.

Dr. Charles S. Turnbull has been appointed major and surgeon of the First Regiment of Pennsylvania.

Through the will of Mrs. Anna Stickler of Camden, N. J., the Methodist Hospital of this city has been left $5000.

A bequest of $15,000 has been made to the Orthopedic Hospital through the will of Ruth Anna Cope, and $1000 was given to the Germantown Hospital.

At a recent meeting of the College of Physicians a life-size oil painting of the late Dr. Joseph Leidy was presented to the college by Mrs. Joseph Leidy, Jr. An autograph letter to Dr. Leidy from Professor T. H. Huxley was also presented to the college. The gifts were received on the part of the college by Dr. S. Weir Mitchell.

In a recent letter to a member of the common council, Dr. John V. Shoemaker presents the needs of the Philadelphia Hospital in rather strong terms. He stated that in one instance 88 children were housed in the hospital together with adults, a condition which is to be deplored from a moral standpoint if for no other. Dr. Shoemaker also made an earnest plea for the erection of a children's hospital in connection with the Philadelphia hospital.

A determined effort is being made by the Philadelphia County Medical Society, the Society for the Prevention of Tuberculosis, and other organizations, to have tuberculosis placed under the compulsory registration law. Looking toward this end, committees of the above societies have appeared before the board of health for the purpose of urging immediate action. What is mainly desired is to know just where the infected houses are located, so that the proper literature and instruction may be sent to the persons affected.

Coroner Dugan states that 2679 inquests were made during the last year, of which 1605 were on white males, 831 on white females, 129 on colored males, and 117 on colored females; 4 were on Mongolians. This is an increase of 120 over the previous year. The principal causes of death were: Injuries, 650; scalds and burns, 160; heart disease, 317; drowning, 92; electric shock, 9; falling or jumping from windows, 18; heat stroke, 61; suffocation from illuminating gas, 43; accidental poisoning, 21; homicides, 35; 173 persons committed suicide. The principal agencies were as follows: hanging, 34; shooting, 40; illuminating gas, 31; laudanum, 15; carbolic acid, 21; cutting and stabbing, 15; drowning, 13; jumping from windows, 5; corrosive and arsenical poisoning, 12. There were 133 deaths from injuries due to steam cars, and 35 deaths from trolley cars.

TENNESSEE.

The Sewanee Medical School, on December 21, graduated 101 students in medicine.

The house of Dr. Goleman D. Sullivan, at Sullivans, Mason county, was burned December 26.

Dr. John H. Harris, Gadsden, sustained a loss of $800 by a fire December 24, which destroyed his office, medicines and instruments.

Lynchburg has elected Dr. Edward M. Dance, a member and ex-officio president of the board of health, and Dr. Thomas H. Woods, alternate member of the board and ex-officio president pro tempore.

Dr. James A. Albright, Nashville, secretary of the State Board of Health, has issued a circular letter to county health-officers stating the smallpox situation, urging vaccination and suggesting that negroes be vaccinated with the hypodermic needle in order that the virus may not be wiped off or the vaccination otherwise rendered ineffectual.

TEXAS.

Dr. Alexander H. Davidson, Boerne, has been appointed physician of Kendall county, and Dr. Arthur F. Newberry, Hallettsville, re-appointed health officer of Lavaca county.

The Democratic Convention at Waco passed the following resolution: "Resolved, That we favor the creation of a State Board of Health with the provision for the collection of vital statistics of the State, as provided for by the Constitution, Article 16, Section 32, and the enactment of laws to distribute the expenses of improvements of quarantine equitably between the State, counties and municipalities."

WISCONSIN.

Riverside Hospital, Wausau, was damaged by fire, December 26, to the extent of $6000. The patients were all removed in safety.

An addition to St. Luke's Hospital, Racine, is to be erected by Mr. and Mrs. William Horlick, in memory of their daughter, which will be known as the "Alice Horlick Memorial." The proposed building will nearly treble the capacity of the hospital.

The State Board of Medical Examiners has submitted its biennial report to the governor. During the last two years the receipts from licenses, registrations and examinations were $8772.52, and the expenses, $7909.21, leaving a balance of $863.31, which has been deposited in the state treasury.

UTAH.

Dr. Oliver S. Ormsby, Logan, has resigned as a member of the State Board of Medical Examiners, on account of removal from the state.

The Attorney-General holds that the State Board of Health has power to enforce the order excluding unvaccinated pupils from public schools in the state.

The Order requiring vaccination of children or their exclusion from school has been made operative in nineteen towns in the state, including Salt Lake City and Ogden.

A phrenologist of Salt Lake City, charged with practicing medicine without a license, was found not guilty, although evidence was presented that he had prescribed medicine. He, however, claimed that he had made no charge for the medicine, but had charged $10 for a phrenological chart.

GENERAL.

Havana reported last week that no case of yellow fever existed among the Americans, and that there were in Luas Guaymas Hospital only 10 persons, all Spaniards, suffering from the disease.

Dr. J. A. Nydegger, passed asst.-surgeon, has arrived at San Francisco from the Philippines, where he has been on quarantine duty. He was taken ill and has been ordered to report to the Chicago Marine-Hospital for duty.

The authorities at Dawson, Yukon, have telegraphed to the outside for 10,000 more vaccin points for use in enforcing the compulsory vaccination ordinance passed recently, to have effect throughout Yukon territory. There are now 2500 points on the way there, making a total of 12,500 ordered.

Dr. J. H. Raymond, formerly an instructor at Rush Medical College, has been appointed president of the Honolulu Board of Health in place of C. B. Wood, M.D., resigned. After about a year's absence in Chicago and San Francisco, he has resumed practice in partnership with Dr. W. J. Galbraith, formerly of Omaha.

The Surgeon-General of the Marine-Hospital Service has caused to be prepared by one of the medical officers of the service a new edition of the handbook of the ships' medicine chest, a small volume written in as plain language as possible for the use of shipmasters and others on board vessels not carrying medical officers. The book is also used at United States life-saving stations.

The Chicago Medical Society, at a meeting held Jan. 2, 1901, adopted the following resolutions: Resolved, that it is the sense of this society that pathological specimens, which are now taxed at 20 per cent. on the cost of their production, should be admitted duty free, as they are used exclusively for scientific purposes and are of no commercial value. Resolved, further, that a copy of this resolution be transmitted to each senator from this state and to each member of Congress from this city.

GOVERNMENT PROVIDES AGAINST DISEASE EPIDEMIC IN THE SOUTH.

The United States Government has just equipped in Florida and placed in readiness for any emergency the largest detention camp in this country. Surgeon-General Wyman states that the camp ground consists of 100 acres of land located on a high bluff on the south side of St. Mary's river, 2½ miles from Boulogne, Fla., and some four or five miles from Folkstone, Ga. On the grounds are a disinfection and warehouse building, two dining-rooms with a seating capacity of 600 people each, a kitchen and storeroom. In the shape of permanent constructions there are officers' quarters. Stored in the now unused dining-rooms are 500 tents, which are capable of easily accommodating 2000 people, should such an emergency arise. Arrangements have been made for the disinfection of all sewage from camps before it is discharged into the river, so that there will be no danger of an outbreak among people drinking the river water below.

PAN-AMERICAN MEDICAL CONGRESS.

The sessions of the sections of the congress will begin on the morning of February 4, in the halls of the University and Institute. In the evening the formal opening ceremonies of the entire Congress, a general session, will take place at the Tacon theater, at which the various representatives of the different countries will be introduced, and speeches of welcome will be made by the officers of the Congress, as well as by the civil authorities. On the second day, scientific sessions of sections will take place; in the evening there will be an entertainment given to the delegates and their families by the City Council of Havana. On the third day, scientific sessions of sections will be in the morning as usual; in the evening a general session dedicated to scientific discourses. On the fourth day, session meetings will be held; in the evening a closing general session in which the officers of the Congress will participate. General Wood, the governor-general of Cuba, formerly surgeon in the U. S. Army, will give a reception to the delegates, probably the day before the opening of the Congress. He will also give orders that the fortifications of the island be shown to the delegates. The insignia or medal of the delegation will be made of silver. On one side will be written, "Third

Pan-American Medical Congress, Havana, 1901." on the other side, will be the coat of arms of Cuba, beneath which the word Cuba is written.

FOREIGN.

DR. EDWIN KLEBS, for the last four years professor at Rush, Chicago, has settled at Munich since his return to Germany.

THE *Muench. Med. Woch.* states that the German Medical Tribunal of Honor has decided that continuous advertising in the lay press is unworthy of the profession, and has consequently imposed a heavy fine on a number thus advertising.

DR. CHAPOT PREVOST, who performed the operation on the xiphopagus monster, has been awarded 40,000 milreis by the Brazilian government as a prize bestowed by the nation and to defray the expenses of his trip to Europe to demonstrate the surviving twin in scientific circles. This sum is normally equivalent to $21,900, and even in the depreciated condition of the currency amounts to about $4000.

A PRESS dispatch from Vienna states that the entire corps of physicians connected with the Lemberg and Cracow hospitals threaten to strike January 12. They demand an increase of salary. At present they are paid on the scale fixed in the reign of Maria Theresa, in 1760. These salaries include such old-fashioned and obsolete perquisites as ten tallow candles monthly.

THE *Bibliographia Medica* has commenced the publication of special editions restricted to a single branch of science, six in all. The first contains the bibliography of anatomy, physiology and the veterinary art, to cost ten francs or $2 a year. The others include medicine, general and special, thirty francs; surgery, general and special, twenty francs; gynecology, obstetrics and pediatrics, fifteen francs, and therapeutics, pharmacy and materia medica, ten francs. The complete edition costs fifty to sixty francs. A complete alphabetical index will be furnished with each special edition for two francs extra, at the end of the year.

THE ANNUAL distribution of prizes at the Paris *Academie de Médecine* occurred December 18. No papers were received from an American author and no articles from any source for five of the prizes. Pagano, of Palermo, was awarded a prize of 1200 francs for his work on the "Sensibility of the Heart and Vessels," and an Alexandria physician received a portion of another prize for his study of the plague in 1899 at his city. The Japanese author whose study of immunity to tuberculosis was reviewed in THE JOURNAL, December 29, p. 1690, and Heresco of Bucharest each received a portion of a prize, the latter for his work on "Surgical Intervention for Tumors of the Kidney." With these exceptions all the prizes were awarded to French authors, which includes Dr. Matignon at Pekin. An hour or two before the session fire broke out in the famous library adjoining the hall, but was soon controlled.

Correspondence.

Foreign Bodies in the Ear.

BINGHAMTON, N. Y., Jan. 5, 1901.

To the Editor:—I write to add my experience in the management of the above cases. A boy was brought to me with a grain of corn in his ear, which had defied all the efforts at removal made by his parents and friends. It had been lodged there for several days. The external ear was swollen to perhaps double its normal size, and the tumefaction of the tissues was such that the auditory canal was nearly closed. Only a small portion of the surface of the grain of corn could be seen. The parts were much inflamed and the tenderness was so acute, that no manipulations or instrumental efforts could be made without an anesthetic. I was, however, able to achieve a most gratifying success by the use of a continuous jet of warm water thrown gently against the ear by a Davidson's syringe, until at last, under these measures the tissues relaxed to such an extent that some of the water ultimately passed behind the kernel of corn, and it was carried out by the returning current.

I have always regarded the use of water poured in the ear as the best mode of removing a live insect. On one occasion during my army service I was called at night to see a soldier into whose ear a hard-shelled beetle had crawled. The insect was so large that its body filled the auditory canal. I seized its outer extremity with a dressing forceps, but they slipped off; the insect's movements made the soldier scream with pain. Close by was the soldier's canteen of water; from it I poured some water into the ear and the invader immediately retreated rear-foremost. J. M. FARRINGTON, M.D.

Goat Lymph.

WESTBORO, Mass., Dec. 24, 1900.

To the Editor: I send herewith a letter recently received which may be interesting to your readers. I thought this communication would inform the medical profession that if there is anything of value in goat-blood serum it can be obtained through regular channels and at a moderate price. By reference to Abbott's "Bacteriology" any physician can prepare his own serum very readily. The expense of a healthy young goat is only about three dollars. W. T. PARKER, M.D.

W. T. Parker, M.D., Westboro:—We have before us your esteemed communication of the 26th inst., advising us to place a goat-blood serum upon the market as a substitute for the goat lymph which is being so extensively advertised as a remedy for chronic diseases. In reply we beg to say that while we do not mention in our catalogue a serum of this kind, we are prepared to supply it upon special requisition, at the rate of $1 per bulb of 10 c.c., or $2.75 per ounce. The serum has been available to the medical profession about a year now; and while we do not make any therapeutic claims in its behalf we think it probable that it will accomplish as much as the lymph to which you refer. We do not consider this a very extravagant claim, for the reason that we have little or no faith in the virtues of the "lymph." Physicians who are interested in experiments on the goat as a therapeutic resource, will find our serum suited to their purpose, at least for a time; they will have the satisfaction of knowing what they are using, as the preparation can be duplicated by any competent biologist who has a healthy goat in his possession. . . . Thanking you sincerely for your suggestion and offer of assistance, and trusting that if you decide to experiment with goat serum you will specify our product and obtain results worthy of publication, we remain, with best regards, very truly yours,

PARKE, DAVIS & CO.

Higher Medical Education and the State University of Iowa.

IOWA CITY, Jan. 7, 1901.

To the Editor:—Knowing your efforts for the advancement of medical education, I believe that you will be interested in hearing that the faculty of the College of Medicine of the State University of Iowa has decided to extend the course to four years of nine months each, the length of the session to be thirty-eight weeks, or thirty-six weeks exclusive of vacations. Last year the Board of Regents granted permission to make such a change in 1902, but by a unanimous vote the medical faculty requested that it might go into effect a year earlier. It has not been the experience of the faculty that an increase in work is followed by a decrease in attendance, as the places of such students as are frightened away are filled by the more desirable material which goes, not where a diploma is the easiest to be obtained, but where the fullest instruction appears to be offered; nevertheless the opinion fully prevails that quality is preferable to quantity and that the college must be kept among the leaders even if the enrollment suffers. The requirements for admission have for some time been the same as for entrance to the College of Liberal Arts of the University, and all preliminary examinations are conducted by the University Examiner, whose certificate alone can give admission. Yours very truly, E. W. ROCKWOOD, M.D.

Association News.

Proposed Legislation Affecting Medical Corps of the U. S. Army.

To the Members of the AMERICAN MEDICAL ASSOCIATION: Your attention is called to the fact that there is at present pending in Congress certain proposed legislation that seriously disturbs the present status and efficiency of the medical corps of the United States army.

The proposed law is entitled: "An Act to Increase the Efficiency of the Military Establishment of the United States" —Senate Bill 4300—and in a general way modifies the existing organization of the army, while at the same time it provides for a damaging and offensively invidious discrimination against

In a recent letter to a member of the common council, Dr. John V. Shoemaker presents the needs of the Philadelphia Hospital in rather strong terms. He stated that in one instance 88 children were housed in the hospital together with adults, a condition which is to be deplored from a moral standpoint if for no other. Dr. Shoemaker also made an earnest plea for the erection of a children's hospital in connection with the Philadelphia hospital.

A determined effort is being made by the Philadelphia County Medical Society, the Society for the Prevention of Tuberculosis, and other organizations, to have tuberculosis placed under the compulsory registration law. Looking toward this end, committees of the above societies have appeared before the board of health for the purpose of urging immediate action. What is mainly desired is to know just where the infected houses are located, so that the proper literature and instruction may be sent to the persons affected.

Coroner Dugan states that 2679 inquests were made during the last year, of which 1605 were on white males, 831 on white females, 129 on colored males, and 117 on colored females; 4 were on Mongolians. This is an increase of 120 over the previous year. The principal causes of death were: Injuries, 650; scalds and burns, 160; heart disease, 317; drowning, 92; electric shock, 9; falling or jumping from windows, 18; heat stroke, 61; suffocation from illuminating gas, 43; accidental poisoning, 21; homicides, 35; 173 persons committed suicide. The principal agencies were as follows: hanging, 34; shooting, 40; illuminating gas, 31; laudanum, 15; carbolic acid, 21; cutting and stabbing, 15; drowning, 13; jumping from windows, 5; corrosive and arsenical poisoning, 12. There were 133 deaths from injuries due to steam cars, and 35 deaths from trolley cars.

TENNESSEE.

The Sewanee Medical School, on December 21, graduated 101 students in medicine.

The house of Dr. Goleman D. Sullivan, at Sullivans, Mason county, was burned December 26.

Dr. John H. Harris, Gadsden, sustained a loss of $800 by a fire December 24, which destroyed his office, medicines and instruments.

Lynchburg has elected Dr. Edward M. Dance, a member and ex-officio president of the board of health, and Dr. Thomas H. Woods, alternate member of the board and ex-officio president pro tempore.

Stored in the now unused dining-rooms are 500 tents, which are capable of easily accommodating 2000 people, should such an emergency arise. Arrangements have been made for the disinfection of all sewage from camps before it is discharged into the river, so that there will be no danger of an outbreak among people drinking the river water below.

PAN-AMERICAN MEDICAL CONGRESS.

The sessions of the sections of the congress will begin on the morning of February 4, in the halls of the University and Institute. In the evening the formal opening ceremonies of the entire Congress, a general session, will take place at the Tacon theater, at which the various representatives of the different countries will be introduced, and speeches of welcome will be made by the officers of the Congress, as well as by the civil authorities. On the second day, scientific sessions of sections will take place; in the evening there will be an entertainment given to the delegates and their families by the City Council of Havana. On the third day, scientific sessions of sections will be in the morning as usual; in the evening a general session dedicated to scientific discourses. On the fourth day, session meetings will be held; in the evening a closing general session in which the officers of the Congress will participate. General Wood, the governor-general of Cuba, formerly surgeon in the U. S. Army, will give a reception to the delegates, probably the day before the opening of the Congress. He will also give orders that the fortifications of the island be shown to the delegates. The insignia or medal of the delegation will be made of silver. On one side will be written, "Third

Pan-American Medical Congress, Havana, 1901." on the other side, will be the coat of arms of Cuba, beneath which the word Cuba is written.

FOREIGN.

Dr. Edwin Klebs, for the last four years professor at Rush, Chicago, has settled at Munich since his return to Germany.

The *Muench. Med. Woch.* states that the German Medical Tribunal of Honor has decided that continuous advertising in the lay press is unworthy of the profession, and has consequently imposed a heavy fine on a number thus advertising.

Dr. Chapot Prevost, who performed the operation on the xiphopagus monster, has been awarded 40,000 milreis by the Brazilian government as a prize bestowed by the nation and to defray the expenses of his trip to Europe to demonstrate the surviving twin in scientific circles. This sum is normally equivalent to $21,900, and even in the depreciated condition of the currency amounts to about $4000.

A press dispatch from Vienna states that the entire corps of physicians connected with the Lemberg and Cracow hospitals threaten to strike January 12. They demand an increase of salary. At present they are paid on the scale fixed in the reign of Maria Theresa, in 1760. These salaries include such old-fashioned and obsolete perquisites as ten tallow candles monthly.

The *Bibliographia Medica* has commenced the publication of special editions restricted to a single branch of science, six in all. The first contains the bibliography of anatomy, physiology and the veterinary art, to cost ten francs or $2 a year. The others include medicine, general and special, thirty francs; surgery, general and special, twenty francs; gynecology, obstetrics and pediatrics, fifteen francs, and therapeutics, pharmacy and materia medica, ten francs. The complete edition costs fifty to sixty francs. A complete alphabetical index will be furnished with each special edition for two francs extra, at the end of the year.

The annual distribution of prizes at the Paris *Academie de Médecine* occurred December 18. No papers were received from an American author and no articles from any source for five of the prizes. Pagano, of Palermo, was awarded a prize of 1200 francs for his work on the "Sensibility of the Heart and Vessels," and an Alexandria physician received a portion of another prize for his study of the plague in 1899 at his city. The Japanese author whose study of immunity to tuberculosis was reviewed in The Journal, December 29, p. 1690, and Heresco of Bucharest each received a portion of a prize, the latter for his work on "Surgical Intervention for Tumors of the Kidney." With these exceptions all the prizes were awarded to French authors, which includes Dr. Matignon at Pekin. An hour or two before the session fire broke out in the famous library adjoining the hall, but was soon controlled.

Correspondence.

Foreign Bodies in the Ear.

Binghamton, N. Y., Jan. 5, 1901.

To the Editor:—I write to add my experience in the management of the above cases. A boy was brought to me with a grain of corn in his ear, which had defied all the efforts at removal made by his parents and friends. It had been lodged there for several days. The external ear was swollen to perhaps double its normal size, and the tumefaction of the tissues was such that the auditory canal was nearly closed. Only a small portion of the surface of the grain of corn could be seen. The parts were much inflamed and the tenderness was so acute, that no manipulations or instrumental efforts could be made without an anesthetic. I was, however, able to achieve a most gratifying success by the use of a continuous jet of warm water thrown gently against the ear by a Davidson's syringe, until at last, under these measures the tissues relaxed to such an extent that some of the water ultimately passed behind the kernel of corn, and it was carried out by the returning current.

I have always regarded the use of water poured in the ear as the best mode of removing a live insect. On one occasion during my army service I was called at night to see a soldier into whose ear a hard-shelled beetle had crawled. The insect was so large that its body filled the auditory canal. I seized its outer extremity with a dressing forceps, but they slipped off; the insect's movements made the soldier scream with pain. Close by was the soldier's canteen of water; from it I poured some water into the ear and the invader immediately retreated rear-foremost. J. M. Farrington, M.D.

Goat Lymph.

Westboro, Mass., Dec. 24, 1900.

To the Editor: I send herewith a letter recently received which may be interesting to your readers. I thought this communication would inform the medical profession that if there is anything of value in goat-blood serum it can be obtained through regular channels and at a moderate price. By reference to Abbott's "Bacteriology" any physician can prepare his own serum very readily. The expense of a healthy young goat is only about three dollars. W. T. Parker, M.D.

W. T. Parker, M.D., Westboro:—We have before us your esteemed communication of the 26th inst., advising us to place a goat-blood serum upon the market as a substitute for the goat lymph which is being so extensively advertised as a remedy for chronic diseases. In reply we beg to say that while we do not mention in our catalogue a serum of this kind, we are prepared to supply it upon special requisition, at the rate of $1 per bulb of 10 c.c., or $2.75 per ounce. The serum has been available to the medical profession about a year now; and while we do not make any therapeutic claims in its behalf we think it probable that it will accomplish as much as the lymph to which you refer. We do not consider this a very extravagant claim, for the reason that we have little or no faith in the virtues of the "lymph." Physicians who are interested in experiments on the goat as a therapeutic resource, will find our serum suited to their purpose, at least for a time; they will have the satisfaction of knowing what they are using, as the preparation can be duplicated by any competent biologist who has a healthy goat in his possession. . . . Thanking you sincerely for your suggestion and offer of assistance, and trusting that if you decide to experiment with goat serum you will specify our product and obtain results worthy of publication, we remain, with best regards, very truly yours,

Parke, Davis & Co.

Higher Medical Education and the State University of Iowa.

Iowa City, Jan. 7, 1901.

To the Editor:—Knowing your efforts for the advancement of medical education, I believe that you will be interested in hearing that the faculty of the College of Medicine of the State University of Iowa has decided to extend the course to four years of nine months each, the length of the session to be thirty-eight weeks, or thirty-six weeks exclusive of vacations. Last year the Board of Regents granted permission to make such a change in 1902, but by a unanimous vote the medical faculty requested that it might go into effect a year earlier. It has not been the experience of the faculty that an increase in work is followed by a decrease in attendance, as the places of such students as are frightened away are filled by the more desirable material which goes, not where a diploma is the easiest to be obtained, but where the fullest instruction appears to be offered; nevertheless the opinion fully prevails that quality is preferable to quantity and that the college must be kept among the leaders even if the enrollment suffers. The requirements for admission have for some time been the same as for entrance to the College of Liberal Arts of the University, and all preliminary examinations are conducted by the University Examiner, whose certificate alone can give admission.

Yours very truly, E. W. Rockwood, M.D.

Association News.

Proposed Legislation Affecting Medical Corps of the U. S. Army.

To the Members of the American Medical Association: Your attention is called to the fact that there is at present pending in Congress certain proposed legislation that seriously disturbs the present status and efficiency of the medical corps of the United States army.

The proposed law is entitled: "An Act to Increase the Efficiency of the Military Establishment of the United States" —Senate Bill 4300—and in a general way modifies the existing organization of the army, while at the same time it provides for a damaging and offensively invidious discrimination against the medical corps. This fact is shown in the following particulars, viz:

1. It decreases the percentage composition of the corps in the grades of colonel from 3.1 per cent. to 2.4 per cent.
2. It changes the percentage composition of the corps in the grade of lieutenant-colonel from 5.2 to 5.7 per cent.
3. It decreases the percentage of composition of the corps in the grade of major from 26 per cent. to 18.6 per cent.
4. It increases the percentage composition of the corps in the grade of assistant-surgeon with the ranks of captain and first lieutenant from 65 per cent. to 74.7 per cent.

The significance of these proposed changes can be understood when it is remembered that even under the existing law it requires more than eighteen years to reach the grade of surgeon with the rank of major, while under the proposed law it will require at least twenty-five years to reach the same grade and rank. With this fact reduced to a mathematical demonstration, the inevitable result will be: 1, that the more worthy young men will not apply for commission, and 2, that the relatively less worthy men who do enter the service, discouraged by the certain impossibility of reasonably prompt promotion, will resign, leaving their places to be filled by untrained and consequently less efficient men. The ultimate disaster from this contemplated change, however, will consist not alone in a lowered status of the medical service, but in 1, increased disease and death-rate among the men, 2, a diminished and otherwise weakened force on the firing line, and 3, a material augmentation of the pension roll.

In view of the foregoing facts, and in view of the fact that every other corps of the army is better graded than is the medical, every member of the American Medical Association and every member of the medical profession is hereby earnestly solicited to send at once to his United States senator and congressman an urgent and emphatic protest against provisions in Senate Bill 4300, relative to the medical corps of the United States army. [Signed] Chas. A. L. Reed,

President of the American Medical Association.

Cincinnati, Dec. 29, 1900.

J. N. Poer, M.D., West Point, Ga., to Miss May Belle Bonnell, Oxford. Ga., January 2.

John W. Maguire, M.D., to Mrs. Bianca St. John, both of Hutchinson, Kas., December 24.

R. Percy Smith, M.D., Baltimore, Md., to Miss Martha E. Elliott, Towson, Md., January 8.

Frank Rogers Rich, M.D., to Miss Francis Louise Yellott, both of Towson, Md., January 1.

Sanders L. Swygert, M.D., Phoenix, S. C., to Miss Myrtis Wells, of Greenwood, S.C., December 20.

Augustus Jerome Thomas, M.D., to Miss Edith Lee Diamond, both of New Orleans, December 19.

William W. Whitney, M.D., Union, N. Y., to Miss Bertha L. Robinson, of Binghamton, December 27.

B. W. Toothaker, M.D., Westmoreland, Kas., to Miss Esther A. Schroer, of St. Joseph, Mo., December 26.

William J. Hodges, M.D., to Miss Helen Asher, both of Pineville, Ky., at Jellico, Tenn., December 28.

William Ivan Senkler, M.D., Vancouver, B.C., to Miss Leila Mackay, of Toronto, Ont., December 19.

R. B. Layman, M.D., South Knoxville, Tenn., to Miss Margaret Pitner, Trundle's Cross Roads, Sevier county, Tenn., December 25.

Deaths and Obituaries.

Louis Schneider, M.D., Kentucky School of Medicine, Louisville, 1865, a prominent physician of Williamsport, Pa., president of the Lycoming county medical society in 1888, at his home, from pneumonia, December 29, aged 56.

William H. Behle, M.D., College of Physicians and Surgeons, Keokuk, Iowa, 1881, a member of The American Medical Association, from blood-poisoning, December 28, at his home in Salt Lake City, Utah, aged 52.

Augustine R. Booth, M.D., University of Louisville, 1874, surgeon in the United States Marine-Hospital Service, at Shreveport, La., after a lingering illness, December 27, aged 56.

Alpharis E. Rundell, M.D., Medical College of Evansville, Ind., 1874, formerly of Center Point, at his home in Brazil, Ind., from Bright's disease, December 28, aged 50.

John DeLamater, M. D., Castleton Medical College, Castleton, Vt., for many years a practitioner at Brooklyn, Mich., suddenly, at Jackson, Mich., December 30, aged 80.

B. Richards, M.D., Jefferson Medical College, Philadelphia, 1850, at his home "Tuckoman," King William County, Va., from cancer of the face, December 25, aged 78.

Mortimer L. Sleeper, M.D., Dartmouth Medical College, Hanover, N. H., 1876, at his home, West Burke, Vt., from diabetes mellitus, December 24, aged 48.

William A. Palmer, M.D., St. Louis College of Physicians and Surgeons, 1879, after a protracted illness at his home in Russell, Iowa, December 20, aged 50.

William Duncan, M.D., Savannah Medical College, 1861, a member of The American Medical Association, at his residence, Savannah, Ga., December 27.

William C. Jones, M.D., Bellevue Hospital Medical College, New York, 1870, at his home in Grass Valley, Cal., from paralysis, December 28, aged 67.

A. B. Denison, M.D., Starling Medical College, Columbus, *Ohio*, 1867, of Shauck, Morrow County, Ohio, December 28, after a long illness, aged 63.

Samuel W. Collins, M.D., University College of Medicine, Richmond, Va., 1898, of Varina, Va., suddenly from heart disease, December 26, aged 30.

Joseph W. Pugh, M.D., Kentucky School of Medicine, Louisville, 1880, at his home in Alexandria, Ind., after a long illness, December 28.

Byron B. Loughead, M.D., Western Reserve University, Cleveland, *Ohio*, *1877*, at his home, Ravenna, Ohio, December 25, aged 53.

Isaac Mayfield, M.D., Medical College of Ohio, Cincinnati, 1870, at his home, Randolph, Kas., from paralysis, December 25, aged 86.

John Whittaker, M.D., Washington University, St. Louis, 1862, at his home, Camden, Ohio, from paralysis, December 24, aged 73.

Charles McKillen, M.D., Medical College of Indiana, Indianapolis, 1873, from apoplexy, at his home in Camden, Mich., aged 51.

Harvey H. Buhrman, M.D., University of Maryland, 1862, at Foxville, Frederick County, Md., January 2, aged 61.

Charles Carroll, M.D., Memphis University Medical College, 1889, at his home, Riverside, Texas, December 27.

Thomas O. Walton, M.D., New York University, 1862, at Annapolis, Md., suddenly, December 21.

Hiram C. Cure, M.D., for 40 years a practitioner at Martinsville, Ind., December 30.

Book Notices.

Bacteriology and Surgical Technique for Nurses. By Emily A. M. Stoney, Superintendent of the Training School for Nurses, St. Anthony's Hospital, Rock Island, Ill. Illustrated. Cloth; pp. 190. Price, $1.25. Philadelphia and London: W. B. Saunders & Co. 1900.

The modern nurse is a product of modern medicine. She, or occasionally he, is a necessity of the conditions produced by the present methods of scientific and humane management of the sick and suffering. The modern nurse, if she be successful, must be an intelligent being, not an automaton or a machine to go mechanically through certain routine duties. She should not only know how, but also why, she does certain things, so that she can do them intelligently. This book is intended to teach the nurse the reason why, so that she may know how, to enter into the details of the scientific nursing of surgical cases. The first chapter on History of Bacteriology places before the reader in a simple manner an account of the growth of the science of bacteriology from its beginning. Following this are chapters on Bacteria as a Cause of Disease, in which the various bacteria of importance and their nature are considered; the Theory of Antitoxins; Antiseptics, Disinfectants and Deodorants, in which are described the various germicidal agents, their nature, uses, etc. In the second part are considered the care of the operating-room, sterilization, care of instruments, keeping of charts, anesthetics, surgical dressings, use of the thermocautery, manner of making saline infusions, etc., preparation and care of sutures, ligatures, drainage-tubes, etc., complications following operations, and their management. In fact, all that a surgical nurse, as such, ought to know is discussed in a sensible manner, the author keeping in mind the fact that she is writing for the nurse, not for the operating surgeon. The book is to be commended.

Modern Surgery, General and Operative. By John Chalmers Da Costa, M.D., Professor of Principles of Surgery and of Clinical Surgery, Jefferson Medical College. With 493 Illustrations. Third Edition, Revised and Enlarged. Cloth; pp. 1117. Price, $5.00 net. Philadelphia and London: W. B. Saunders & Co. 1900.

In this edition Da Costa has brought his well-known work thoroughly up to date, making it, as its name indicates, a "modern" surgery. The general plan of former editions has been retained.

A Reference Handbook of the Medical Sciences. Embracing the Entire Range of Scientific and Practical Medicine and Allied Science. By Various Writers. A New Edition. Completely Revised and Rewritten. Edited by Albert H. Buck, M.D., New York City. Volume I. Illustrated by Numerous Chromolithographs and 498 fine Half-Tone and Wood Engravings. Cloth. Pp. 799. Price, $7.00. New York: Wm. Wood & Co. 1900.

The "Reference Hand-Book of the Medical Sciences," one of the great encyclopedic works on medicine, is being revised, and the first volume of the new edition is before us. The first volume of the original work was issued in the fall of 1885, and the last in 1887, thirteen years ago. To bring out a revised edition of such a work is no small undertaking, but if it is to continue to fill the place it occupied, the re-writing of the book is necessary. The changes and the advancement of the last decade and a half have made the greater part of the work obsolete. Comparing the first volume of the new with the first volume of the old, one realizes that most of the matter has been re-written. While occasionally the same article is reproduced, this is exceptional, and not only is the new rewritten, but, as a rule, by a different author. The changes that have taken place in medicine in the short fifteen years the medical corps. This fact is shown in the following particulars, viz:

1. It decreases the percentage composition of the corps in the grades of colonel from 3.1 per cent. to 2.4 per cent.
2. It changes the percentage composition of the corps in the grade of lieutenant-colonel from 5.2 to 5.7 per cent.
3. It decreases the percentage of composition of the corps in the grade of major from 26 per cent. to 18.6 per cent.
4. It increases the percentage composition of the corps in the grade of assistant-surgeon with the ranks of captain and first lieutenant from 65 per cent. to 74.7 per cent.

The significance of these proposed changes can be understood when it is remembered that even under the existing law it requires more than eighteen years to reach the grade of surgeon with the rank of major, while under the proposed law it will require at least twenty-five years to reach the same grade and rank. With this fact reduced to a mathematical demonstration, the inevitable result will be: 1, that the more worthy young men will not apply for commission, and 2, that the relatively less worthy men who do enter the service, discouraged by the certain impossibility of reasonably prompt promotion, will resign, leaving their places to be filled by untrained and consequently less efficient men. The ultimate disaster from this contemplated change, however, will consist not alone in a lowered status of the medical service, but in 1, increased disease and death-rate among the men, 2, a diminished and otherwise weakened force on the firing line, and 3, a material augmentation of the pension roll.

In view of the foregoing facts, and in view of the fact that every other corps of the army is better graded than is the medical, every member of the American Medical Association and every member of the medical profession is hereby earnestly solicited to send at once to his United States senator and congressman an urgent and emphatic protest against provisions in Senate Bill 4300, relative to the medical corps of the United States army. [Signed] Chas. A. L. Reed,

President of the American Medical Association.

J. N. Poer, M.D., West Point, Ga., to Miss May Belle Bonnell, Oxford, Ga., January 2.

John W. Maguire, M.D., to Mrs. Bianca St. John, both of Hutchinson, Kas., December 24.

R. Percy Smith, M.D., Baltimore, Md., to Miss Martha E. Elliott, Towson, Md., January 8.

Frank Rogers Rich, M.D., to Miss Francis Louise Yellott, both of Towson, Md., January 1.

Sanders L. Swygert, M.D., Phoenix, S. C., to Miss Myrtis Wells, of Greenwood, S.C., December 20.

Augustus Jerome Thomas, M.D., to Miss Edith Lee Diamond, both of New Orleans, December 19.

William W. Whitney, M.D., Union, N. Y., to Miss Bertha L. Robinson, of Binghamton, December 27.

B. W. Toothaker, M.D., Westmoreland, Kas., to Miss Esther A. Schroer, of St. Joseph, Mo., December 26.

William J. Hodges, M.D., to Miss Helen Asher, both of Pineville, Ky., at Jellico, Tenn., December 28.

William Ivan Senkler, M.D., Vancouver, B.C., to Miss Leila Mackay, of Toronto, Ont., December 19.

R. B. Layman, M.D., South Knoxville, Tenn., to Miss Margaret Pitner, Trundle's Cross Roads, Sevier county, Tenn., December 25.

Deaths and Obituaries.

Louis Schneider, M.D., Kentucky School of Medicine, Louisville, 1865, a prominent physician of Williamsport, Pa., president of the Lycoming county medical society in 1888, at his home, from pneumonia, December 29, aged 56.

William H. Behle, M.D., College of Physicians and Surgeons, Keokuk, Iowa, 1881, a member of The American Medical Association, from blood-poisoning, December 28, at his home in Salt Lake City, Utah, aged 52.

Augustine R. Booth, M.D., University of Louisville, 1874, surgeon in the United States Marine-Hospital Service, at Shreveport, La., after a lingering illness, December 27, aged 56.

Alpharis E. Rundell, M.D., Medical College of Evansville, Ind., 1874, formerly of Center Point, at his home in Brazil, Ind., from Bright's disease, December 28, aged 50.

John DeLamater, M. D., Castleton Medical College, Castleton, Vt., for many years a practitioner at Brooklyn, Mich., suddenly, at Jackson, Mich., December 30, aged 80.

B. Richards, M.D., Jefferson Medical College, Philadelphia, 1850, at his home "Tuckoman," King William County, Va., from cancer of the face, December 25, aged 78.

Mortimer L. Sleeper, M.D., Dartmouth Medical College, Hanover, N. H., 1876, at his home, West Burke, Vt., from diabetes mellitus, December 24, aged 48.

William A. Palmer, M.D., St. Louis College of Physicians and Surgeons, 1879, after a protracted illness at his home in Russell, Iowa, December 20, aged 50.

William Duncan, M.D., Savannah Medical College, 1861, a member of The American Medical Association, at his residence, Savannah, Ga., December 27.

William C. Jones, M.D., Bellevue Hospital Medical College, New York, 1870, at his home in Grass Valley, Cal., from paralysis, December 28, aged 67.

A. B. Denison, M.D., Starling Medical College, Columbus, Ohio, 1867, of Shauck, Morrow County, Ohio, December 28, after a long illness, aged 63.

Samuel W. Collins, M.D., University College of Medicine, Richmond, Va., 1898, of Varina, Va., suddenly from heart disease, December 26, aged 30.

Joseph W. Pugh, M.D., Kentucky School of Medicine, Louisville, 1880, at his home in Alexandria, Ind., after a long illness, December 28.

Byron B. Loughead, M.D., Western Reserve University, Cleveland, Ohio, 1877, at his home, Ravenna, Ohio, December 25, aged 53.

Isaac Mayfield, M.D., Medical College of Ohio, Cincinnati, 1870, at his home, Randolph, Kas., from paralysis, December 25, aged 86.

John Whittaker, M.D., Washington University, St. Louis, 1862, at his home, Camden, Ohio, from paralysis, December 24, aged 73.

Charles McKillen, M.D., Medical College of Indiana, Indianapolis, 1873, from apoplexy, at his home in Camden, Mich., aged 51.

Harvey H. Buhrman, M.D., University of Maryland, 1862, at Foxville, Frederick County, Md., January 2, aged 61.

Charles Carroll, M.D., Memphis University Medical College, 1889, at his home, Riverside, Texas, December 27.

Thomas O. Walton, M.D., New York University, 1862, at Annapolis, Md., suddenly, December 21.

Hiram C. Cure, M.D., for 40 years a practitioner at Martinsville, Ind., December 30.

Book Notices.

Bacteriology and Surgical Technique for Nurses. By Emily A. M. Stoney, Superintendent of the Training School for Nurses, St. Anthony's Hospital, Rock Island, Ill. Illustrated. Cloth; pp. 190. Price, $1.25. Philadelphia and London: W. B. Saunders & Co. 1900.

The modern nurse is a product of modern medicine. She, or occasionally he, is a necessity of the conditions produced by the present methods of scientific and humane management of the sick and suffering. The modern nurse, if she be successful, must be an intelligent being, not an automaton or a machine to go mechanically through certain routine duties. She should not only know how, but also why, she does certain things, so that she can do them intelligently. This book is intended to teach the nurse the reason why, so that she may know how, to enter into the details of the scientific nursing of surgical cases. The first chapter on History of Bacteriology places before the reader in a simple manner an account of the growth of the science of bacteriology from its beginning. Following this are chapters on Bacteria as a Cause of Disease, in which the various bacteria of importance and their nature are considered; the Theory of Antitoxins; Antiseptics, Disinfectants and Deodorants, in which are described the various germicidal agents, their nature, uses, etc. In the second part are considered the care of the operating-room, sterilization, care of instruments, keeping of charts, anesthetics, surgical dressings, use of the thermocautery, manner of making saline infusions, etc., preparation and care of sutures, ligatures, drainage-tubes, etc., complications following operations, and their management. In fact, all that a surgical nurse, as such, ought to know is discussed in a sensible manner, the author keeping in mind the fact that she is writing for the nurse, not for the operating surgeon. The book is to be commended.

Modern Surgery, General and Operative. By John Chalmers Da Costa, M.D., Professor of Principles of Surgery and of Clinical Surgery, Jefferson Medical College. With 493 Illustrations. Third Edition, Revised and Enlarged. Cloth; pp. 1117. Price, $5.00 net. Philadelphia and London: W. B. Saunders & Co. 1900.

In this edition Da Costa has brought his well-known work thoroughly up to date, making it, as its name indicates, a "modern" surgery. The general plan of former editions has been retained.

A Reference Handbook of the Medical Sciences. Embracing the Entire Range of Scientific and Practical Medicine and Allied Science. By Various Writers. A New Edition. Completely Revised and Rewritten. Edited by Albert H. Buck, M.D., New York City. Volume I. Illustrated by Numerous Chromolithographs and 498 fine Half-Tone and Wood Engravings. Cloth. Pp. 799. Price, $7.00. New York: Wm. Wood & Co. 1900.

The "Reference Hand-Book of the Medical Sciences," one of the great encyclopedic works on medicine, is being revised, and the first volume of the new edition is before us. The first volume of the original work was issued in the fall of 1885, and the last in 1887, thirteen years ago. To bring out a revised edition of such a work is no small undertaking, but if it is to continue to fill the place it occupied, the re-writing of the book is necessary. The changes and the advancement of the last decade and a half have made the greater part of the work obsolete. Comparing the first volume of the new with the first volume of the old, one realizes that most of the matter has been re-written. While occasionally the same article is reproduced, this is exceptional, and not only is the new re-written, but, as a rule, by a different author. The changes that have taken place in medicine in the short fifteen years is graphically depicted when the two are compared. The article on "Antiseptics in Surgery"—contributed by Surgeon-General Sternberg—is entirely new. In the former edition this was illustrated with cuts showing the memorable spray which Lawson Tait ridiculed so much; another showed an operation with the operator and his assistants in ordinary street apparel, which certainly looks strange nowadays. Another noticeable difference is that the word "appendicitis" is not to be found in the old, but the subject in the new occupies thirteen columns. Autointoxication was not considered fifteen years ago. but now it takes up six full pages. The subject "bacteria" in the old was worthy of only a half column, in the new it claims no less than forty-four pages. This is, by the way, a most excellent monograph of itself, written by Arthur R. Guerard, and beautifully illustrated, showing the various pathogenic bacteria. This large amount of new matter has made it necessary to omit much that appeared in the first edition. But the articles for omission have been carefully selected so that little that is of importance has been expunged. The subject of balneo-therapeutics, which occupied eight pages in the former edition, is omitted entirely, which will be regretted by but few. The illustrations in the new show the advancement made in the illustrator's art. The paper and presswork are both of better quality. If the succeeding volumes take up as much proportionate space as this one, the complete work will be much larger than its predecessor. The new volume only gets as far as "bladder," while the former first volume reached the word "cataract."

Atlas and Epitome of Gynecology. By Dr. Oskar Schaeffer, Privat-Docent of Obstetrics and Gynecology in the University of Heidelberg. Authorized Translation from the Second Revised and Enlarged German Edition. Edited by Richard C. Norris, A.M., M.D., Surgeon-in-charge, Preston Retreat, Philadelphia. With 207 Colored Illustrations on 90 Plates, and 62 Illustrations in the Text. Cloth; pp. 272. Price, $3.50. W. B. Saunders & Co. 1900.

This compact little work, which is very full of illustrations, is hardly in the usual form of an atlas, though fully deserving of that name. Its value to the medical student will be found, as the editor states, specially in the illustrations. The concise explanatory descriptions are, of course, a valuable feature, and the translation has been well done. The editor has also inserted here and there an editorial comment where it would seem necessary to harmonize and point out the difference between the author's teaching and the usual American practice. The work promises for itself a wide sale and to be of much value to the American student and practitioner.

Hernia: Its Etiology, Symptoms and Treatment. By W. McAdam Eccles, M.S. (Lond.), F.R.C.S. (Eng.), Assistant Surgeon West London Hospital. Cloth. Pp. 231. Price, $2.50. New York: Wm. Wood & Co. 1900.

The aim of this book, as stated in the preface, is "to submit a short account of the origin, symptoms and treatment of a lesion which, by its very frequency, is of considerable importance and one that teems with practical suggestions." The subject is not exhaustively handled, and some of the rarer conditions, such as double sacs, hernia "par glissement;" femoral hernia external to the vessels, pectineal hernia, tuberculosis of the hernial sac, the very large herniæ, etc., are scarcely mentioned. The statement that a direct inguinal hernia is, strictly speaking, a hernia of the linea semilunaris at its lowest part finds no justification in anatomic facts, and it is very doubtful indeed if the conjoined tendon ever actually forms a covering to these herniæ as stated. The indications for the radical operation are too closely drawn. Owing to the very low mortality and the excellent results which follow the modern operation for hernia, it might be said that the presence of a hernia is sufficient indication for operation and that it is only necessary to point out the contraindications or reasons why an operation should not be performed. On account of the fact that late suppuration with extrusion of buried non-absorbable sutures so frequently occurs, the use of the buried silk sutures, as recommended by the author, will find few, if any, adherents on this side of the water.

The treatment of hernia by means of trusses is very well detailed and the illustrations in this connection are unusually good. Many valuable points on the selection and fitting of trusses will be found which show a large and practical experience in this line of work. The author's style is clear, brief and concise, and the volume neatly and well put up.

A Practical Treatise on Fractures and Dislocations. By Lewis A. Stimson, B.A., M.D., LL.D. (Yalen), Professor of Surgery in Cornell University Medical College, New York. Third Edition, Revised and Enlarged. With 336 Illustrations and 32 Plates in Monotint. Cloth Pp. 842. Price, $5.00. New York and Philadelphia: Lea Bros. & Co. 1900.

Only a year has elapsed since the second edition of this book was reviewed in these columns. That a third edition should become necessary in the short space of one year is a recommendation of which few books can boast. Nor is this simply a re-issue. The work has been considerably enlarged by the addition of much new matter and many new plates. The experience of the author with fractures and dislocations has been unusually extensive and, while the work of others has been duly noted and recorded, his conclusions are nearly all based on the large amount of material which has been under his personal care. In considering the ambulatory treatment of fractures, the dangers, as well as the advantages, are clearly defined and the cases in which it is advisable to employ the method pointed out. The operative treatment of acute fractures, such as of the patella and olecranon, is conservatively and judiciously discussed, and advice given to the general practitioner as well as to the experienced hospital surgeon. The author still maintains, as in his former edition, that "thus far, in my experience, the X-rays have rarely given practically important information in fractures which could not have been obtained without their aid." He adds, however, "but there is reason to anticipate that with increasing knowledge and experience much good will yet come from their use." Notwithstanding this rather depreciative estimate of the value of the X-ray, the work is extensively illustrated with excellent X-ray views of nearly all the principal fractures and dislocations. The work is a standard one and can be recommended to all who have to deal with these troublesome cases.

Ballinger and Wippern on the Eye, Ear, Nose and Throat. A Pocket Text-Book of Diseases of the Eye, Ear, Nose and Throat, for Students and Practitioners. By William L. Ballinger, M.D., Assistant Professor of Otology, Rhinology and Laryngology in the College of Physicians and Surgeons, Chicago, etc., and A. G. Wippern, M.D., Professor of Ophthalmology and Otology in the Chicago Eye, Ear, Nose and Throat College. In one handsome 12mo. Pp. 525, with 150 engravings and 6 full-page plates. Cloth, $2.00. Philadelphia and New York: Lea Brothers & Co. 1900.

This compact little volume of related subjects will unquestionably be found useful by the student and the general practitioner. There are in it some magnificent plates descriptive of ocular anatomy. The physiologic tests used by aurists in locating deviations of hearing are dwelt upon at some length. The type and paper are excellent.

Venereal Diseases: Their Complications and Sequelae. By Edward L. Keyes, A.M., M.D., Late Professor of Dermatology and Genito-Urinary Surgery in the Bellevue Hospital Medical College, and Charles H. Chetwood, M.D., Professor of Genito-Urinary Surgery in the New York Polyclinic College and Hospital. Illustrated by 8 Full-Page Plates in Black and Colors, and 107 Engravings. Cloth. Pp. 356. Price, $2.75. New York: Wm. Wood & Co. 1900.

Although a former work of identical title by the senior author of this volume appeared some twenty years ago, this is in no sense a subsequent edition of the work. Dr. Keyes holds his old views, which have been largely accepted by the profession, as to the treatment of syphilis, and he makes no radical change in this presentation of his subject. As regards the teachings of urethral diseases, however, the older work has, he says, long ceased to be a safe guide, and here the work of the junior author is more to the front. The chapter on nervous syphilis has been contributed by Dr. Pearce Bailey, which is duly acknowledged by the authors. The illustrations are numerous, and the more recent views of the different subjects are, we believe, fairly and fully set forth. The compass of the work is sufficient to give a very fair idea of its subject, and while we make no special criticisms or commendations we would say that as a whole it is a very valuable treatise and addition to the literature.

Food and the Principles of Dietetics. By Robert Hutchinson, M.D. Edin., M.R.C.P., Assistant Physician to the London Hospital. With Plates and Diagrams. Cloth. Pp. 548. Price, $5.00. New York: Wm. Wood & Co. 1901.

This volume contains a course of lectures to the students of the London Hospital, recast for publication with a considerable amount of additional matter. It is an excellent manual of dietetics in a form that ought to render it one of the most popular text-books on its subject in our language. Although it is written somewhat from the English rather than the American standpoint, this is not a defect, as the differences that would exist in a purely American work would be slight. The author acknowledges his indebtedness to the American school of investigators in this department, more especially to Prof. Atwater and his colleagues, who have done as much as other recent investigators in any part of the world to advance the science of dietetics. The style of the work is taking, and it is certainly easy reading, which is an advantage; we can safely say that the volume should be of value to the practitioner.

Diseases of the Genito-Urinary System. A Thorough Treatise on Urinary and Sexual Surgery. By Eugene Fuller, M.D., Professor of Genito-Urinary and Venereal Diseases in the New York Post-Graduate Medical School. Cloth. Pp. 774. Price, $5.00. New York: The MacMillan Co. 1900.

This is a treatise on the genito-urinary diseases, largely in their more practical surgical aspects. As they are usually considered surgical diseases this is probably the natural treatment of the subject. The volume covers its ground fairly well. While on some points there may be a difference of opinion as to special methods and ideas described or inculcated, as a whole it is one of the most valuable of the recent contributions to the literature on the subject.

A Text-book of Histology, Including Microscopic Technic. By A. A. Böhm, M.D., and M. von Davidoff, M.D., of the Anatomical Institute in Munich. Edited, with Extensive Additions to both Text and Illustrations, by G. Carl Huber, M.D., Junior Professor of Anatomy and Director of the Histologic Laboratory, University of Michigan. Authorized Translation from the Second Revised German Edition by Herbert H. Cushing, M.D., Demonstrator of Histology and Embryology, Jefferson Medical College, Philadelphia. With 351 Illustrations. Cloth. Pp. 501. Price $3.50. Philadelphia: W. B. Saunders & Co. 1900.

This important volume is one of the numerous additions to English medical literature by the translation of standard German and other foreign works. In this case it is the authorized translation from the second revised German edition edited by Prof. Huber, of the University of Michigan. The substance of the book is the special matter of the lectures and courses in histology given at the University of Munich, and is retained in its English form with certain minor changes and numerous additions by the editor. These are more particularly notable in the portion on the nervous system and the glands of internal secretion. Over 100 illustrations, most of which are from original drawings, have been added to this volume which were not contained in the German editions, making the work as it stands a decided improvement over the original. The translation appears to be admirably done, and the publisher's part is beyond criticism.

Diseases of the Nervous System. A Text-Book for Students and Practitioners of Medicine. By H. Oppenheim, M.D., Professor at the University of Berlin. Authorized Translation by Edward E. Mayer, A.M., M.D., Pittsburg, Pa. First American from the Second Revised and Enlarged German Edition. With 293 Illustrations. Cloth. Pp. 899. Price $5.00. Philadelphia and London: J. B. Lippincott Co. 1900.

Oppenheim's work has acquired a reputation as a text-book in Germany, and the present translation into English is a service to the American profession. As a text-book it is brief in its treatment of many subjects, but its arrangement and its subject-matter are such that it will undoubtedly take its place among other well-known and excellent treatises on nervous diseases that already exist in our language. We do not say that it has special advantages over all of these, but it certainly will be useful and valuable to the student and practitioner as giving the later German views on this important class of disorders.

Tropical Diseases. A Manual of the Diseases of Warm Climates. By Patrick Manson, C.M.G., M.D., LL.D. (Aberd.), Lecturer on Tropical Diseases at St. George's Hospital, Charing Cross Hospital Medical Schools, Lecturer in the London School of Tropical Medicine, Medical Adviser to the Colonial Office, etc. With 114 Illustrations and 2 Colored Plates. Revised and Enlarged Edition. Cloth. Pp. 684. Price $3.50. London, Paris, New York and Melbourne: Cassell & Co., Ltd. 1900.

This manual of diseases of warm climates is handy, compact and concise, and yet appears to contain everything essential for an efficient working knowledge of the diseases of our warmer regions. The chapters on malaria are clear and lucid, and moreover interesting from the fact that Manson first formulated the mosquito-malaria theory, subsequently apparently demonstrated by Ross and MacCallum. The author's scientific turn of mind is apparent in every chapter.

A Text-book of the Practice of Medicine. By James M. Anders, M.D., Ph.D., LL.D., Professor of Practice of Medicine and Clinical Medicine in the Medico-Chirurgical College, Philadelphia. Illustrated. Fourth Edition, Thoroughly Revised. Cloth. Pp. 1292. Price, $5.50 net. Philadelphia and London: W. B. Saunders & Co. 1900.

The fourth edition of this well-known text-book appears only a year later than the previous one, and shows how well it has taken with the medical profession and the student. The changes that have been made are particularly in the parts on diseases of the digestive system and on certain other disorders, together with more or less revision in the text of the remaining portions. As a whole, the present edition is much improved. and there is no question that it will continue to maintain the favor with which it has been heretofore received.

Miscellany.

Proposed Legislation Affecting Army Medical Corps.

The Committee on National Legislation has been in conference with the military committee of the senate and house of representatives considering the army efficiency bill, S. 4300, and has recommended a substitute for Medical Section 18, in the interest of the civilian physicians of the United States and of the surgeon-general. The committee on national legislation appeals to every member of the American Medical Association requesting him to write or telegraph at once to both chairmen, Senator Hawley and Representative Hull, or his individual senator and congressman, urging them to vote for and favor the passage of the substitute presented by the committee. The original bill is highly objectionable. The substitute proposed by the surgeon-general to Section 18 of the Bill, S. 4300, and approved by the Committee on National Legislation of the American Medical Association was printed in The Journal of December 29, p. 1684. We also direct attention to the letter from Dr. C. A. L. Reed in this issue. The substituted section is recommended for the following reasons: The number of medical officers proposed by S. 4300 is 8 colonels, 12 lieutenant-colonels, 60 majors, and 240 captains and lieutenants; a total of 320. This gives a proportion of officers in each grade of 1 colonel. 1½ lieutenant colonels, 7½ majors, 30 captains and lieutenants; a total of 40. The number proposed in the section hereto appended is 10 colonels, 20 lieutenant-colonels, 80 majors, 200 captains and lieutenants; a total of 310, the proportion of officers in each grade being 1 colonel, 2 lieutenant-colonels. 8 majors, 20 captains and lieutenants; a total of 31. The total number asked for, 310, is desired for the reason that it is the absolute minimum number required to properly care for an army of 58,000 men in time of peace. The number of officers in each grade is arrived at for three reasons: 1. That the number of officers in the higher grades is the minimum number required in these grades to properly administer the affairs of the Medical Department. 2. That the number of officers in each grade is within a fraction of the relative number in each grade in the Medical Department at the present time, the present proportion being 1, 1 2/3, 8 1/3, and 20; the proposed proportion being 1, 2, 8 and 20. From this it will be seen that the proportionate rank in the number proposed in this section is within a fraction of the proportionate rank as it now exists in the Medical Department, and that, consequently, no injustice will be done the Medical Department by substituting the proposed numbers for those which now obtain. 3. The efficiency of the Medical Department depends upon the quality of the men who enter this department, and the quality of the men depends upon the inducements offered them to enter upon a life career in the military service. The efficiency of the Medical Department in the past has been maintained by the rank and pay secured by the grading of the officers, which now obtains, and this depends upon the relative number of officers in each grade. It has been shown that the relative number in each grade is practically similar in the proposed section to that which now obtains in the Medical Department. This proportion is much changed by S. 4300, for while the present proportion is 1, 1 2/3, 8 1/3, and 20, total 31, the proportion in S. 4300 is 1, 1½, 7½ and 30—a total of 40; while S. 4300 gives a slightly higher proportion in the higher grades it gives a much lower proportion in the lower grades, the difference in the lower grades being in proportion of 20 to 30, and if S. 4300 becomes a law the consequence will be that while officers in the upper grades will pass through these grades as rapidly as they did before, promotion for officers in the lower grades will be much slower. As at present constituted a majority in the Medical Department is reached after from 18 to 19 years' service, while if S. 4300 is adopted it will take over 25 years for an officer to reach the same grade. For this reason the adoption of S. 4300 could not but seriously impair the future efficiency of the corps, in that by materially reducing the emoluments, it would in the future offer too small an inducement to that class of professional men whose entry to the corps maintains its efficiency. It is believed that the adoption of the numbers in the section proposed will not only give the extreme minimum total number required for the Medical Department in time of peace, and the minimum number of officers of each grade necessary to perform the administrative work of the corps, but by giving practically the same proportion in each grade will enable the medical corps to maintain its present degree of efficiency, in that the same emoluments will be offered in the future as have been offered in the past. The continuance in service for a limited time of a certain number of volunteer surgeons is also recommended. This, for the reason that the exigencies of the service as they now exist in the Philippine Islands can not be met unless more medical officers are allowed than these give for the regular Medical Department. The exigencies of the service demand that these officers shall have the rank of major and colonel, as they have important and arduous duties to perform. Their period of service is limited, in that they are to be retained only so long as their services are necessary and in no case beyond two years after the passage of the act. The appointment of these officers serves a triple purpose in that it allows the retention in service of officers now holding important positions, allows a certain reward to those volunteer medical officers whose services have been of value in the past and gives them time and opportunity to prepare for the examination necessary for entry to the regular medical corps or to adjust their affairs prior to return to civil life. Another provision in the appended section follows the same lines. It provides that in emergency the President is authorized to appoint as many surgeons of volunteers with the rank of first lieutenant as may be necessary, subject to discharge whenever their services are no longer required. This proviso is important in that it allows the President to give an honorable title and position to contract surgeons of long service or special merit. This allows in large part the doing away with the contract surgeon system, using contract surgeons only for brief emergencies, and substituting for civilian quasi-officers a body of men who have the real military rank which is so necessary to a proper performance of the duties of a medical officer in the army. In no other staff corps or branch of the army are civilians employed to occupy the places and perform the duties properly belonging to commissioned officers, and medical men when occupying such positions in the army should have the rank to which their position entitles them and the efficient performance of their duties demands. The volunteer surgeons will act as "feeders" for the regular Medical Department in that their military training will stand them in good stead when they appear before an examining board should they desire to enter the regular medical corps; while, should they return to civil life, they will have the prestige of having been officers in the United States Army should they desire to do duty in the National Guard, or return to the service in time of war. Nor will the cost to the United States be thereby increased. A sufficient number of properly qualified surgeons can not be obtained unless commissions are offered, and every appointment of an inefficient surgeon is a source of expense to the government through the pension claims of his patients and their dependents. The proposed change will also result in large immediate economies to the government. A contract surgeon is not under military rules to the extent of a commissioned officer, and consequently he can and does leave the service before he has more than fairly learned his duties. This results in a constant change of personnel at a heavy direct cost for their pay and expenses while traveling, and also an indirect cost resulting from their military inexperience. The giving of commissions to these surgeons would not change their pay except that when serving in the United States it would be reduced about $300 a year. There would be no difference in the matter of pensions, as the contract surgeon now receives by law the same pension as if he held the commission herein proposed. For these reasons, namely, on the score of efficiency, economy, and justice to men occupying important positions in the medical department, these men should be given the rank and position of officers. The necessity for appointment of such officers whenever necessary is apparent. The officers of the regular Medical Department are only sufficient in number to care for an army of 58,000 men when on a peace footing. In consequence provision must be made to establish an elastic medical corps. This is effected by this proviso, in that in sudden emergency or while the army is above its minimum strength it makes provision for a suitable number of medical officers who are to be retained only for the time when their services are necessary. The substitution of the proposed section for Section 18 and its amendment as it now stands in S. 4300 is, therefore, strongly advocated in that it will give a proper and efficient Medical Department with a properly proportioned minimum number of medical officers for duty with an army of 58,000 men in time of peace and an elastic Medical Department by which emergencies may be met.

H. L. E. Johnson,
Chairman of Committee on National Legislation.

Koch's Report on Malaria.—Koch publishes in the *Deu. Med. Woch.* of December 6 and 13, a summary of the results accomplished by his malaria expedition. He reiterates that examination of the children is the best means to determine the presence and character of malarial infection in a place. In the peculiarly isolated aboriginal villages he visited in eastern Africa, he found it almost universal among the small children. A certain proportion succumb, but the remainder as they grow up seem to acquire a natural immunity by the fifth to tenth year and after that age develop into remarkably fine physique and health, even in the most intensely malarial localities. The children are never treated for malaria; quinin is never given them, and consequently the immunity attained can not be compared with other regions where the natural course of the disease and the process of immunization are interfered with by medicinal measures. He found among the islands of the Bismarck archipelago that some of the islands were entirely free from malaria while others had only one or all three forms. The immunity acquired in an island where only the quartan variety prevailed, for instance, did not protect against the tertian or tropical fever or vice versa. He is convinced that man and mosquitoes are the only hosts of the parasites, and that by curing the infected children and all, even the deceptive, latent cases in adults, malaria can be exterminated. He recommended 1 gm. quinin in solution, taken on a nearly empty stomach in the morning, every tenth and also eleventh day. If fever still persists, the dose can be increased to 1.5 gm., reducing the interval to one and two days. He warns that quinin is not absorbed unless the gastric reaction is acid.

Technique of Transfusion of Blood.—Weintraud described his method of blood transfusion as an improvement over those generally in vogue. He applies a ligature to the arm tight enough to arrest the venous but not the arterial circulation. The pressure is sufficient to send the blood through a tube into the elbow vein of the patient. A second tube at right angles to the first brings salt solution to mix with the blood. The process is so simple that it can be repeated indefinitely. Experiments on animals and clinical experiences show that about 150 to 200 c.c. of blood is transfused in six to ten minutes by this technique.

Societies.

COMING MEETINGS.

Pan-American Medical Congress, Havana, Cuba, Feb. 4, 1901.

Tri-State Medical Association of the Carolinas and Virginia, Richmond, Va., Feb. 26. 1901.

THE BROOKLYN (N. Y.) SOCIETY FOR NEUROLOGY held its annual meeting December 27. Dr. William H. Haynes was elected president and Dr. Bronislaw Onuf secretary.

THE MAINE STATE SANATORIUM ASSOCIATION was organized at Augusta, December 29, with Dr. John F. Hill, as president, and Dr. Albion G. Young, secretary, both of Augusta.

THE WARREN COUNTY (N. Y.) MEDICAL ASSOCIATION has been organized at Glens Falls, with Dr. Godfred R. Martine, president; Dr. David J. FitzGerald, vice-president, and Dr. Fred G. Fielding, secretary and treasurer.

THE ATLANTA (Ga.) SOCIETY OF MEDICINE held its annual meeting, December 20, and elected Dr. T. Virgil Hubbard, president; Dr. Bernard Wolff, vice-president; Dr. Claude A. Smith, secretary, and Dr. Emil Van Goidstnoven, treasurer.

THE MEMPHIS (Tenn.) MEDICAL SOCIETY met December 28 and elected Dr. Frank A. Jones president; Dr. Alfred Moore, vice-president; Dr. James L. Andrews, secretary, and Dr. Richmond McKinney, reporter.

THE GERMAN MEDICAL SOCIETY, Cleveland, O., held its second annual meeting December 20, and elected Dr. Caspar Schmitz, president; Dr. Isidor Belkowsky, vice-president; Dr. Max Kahn, secretary, and Dr. Leo Reich, corresponding secretary.

THE MINNESOTA ASSOCIATION OF MILITARY SURGEONS met for organization at St. Paul, December 29, adopted a constitution and by-laws, and elected Lt.-Col. Reynaldo J. Fitzgerald, Minneapolis, president; Major William Jacoby, Wells, vice-president, and Capt. Geo. M. Coon, secretary and treasurer.

THE CLINTON COUNTY (Pa.) MEDICAL SOCIETY, at its meeting, December 21, nominated Dr. John K. Gilmore, Westport, for president; Dr. Robert B. Watson, Lock Haven, for secretary; Dr. Luther M. Holloway, Salona, for treasurer, and also named its delegates to the State Medical Society and THE AMERICAN MEDICAL ASSOCIATION.

THE LOS ANGELES COUNTY (Cal.) MEDICAL ASSOCIATION, at its annual meeting held December 21, elected Dr. H. Bert Ellis, Los Angeles, president;Dr. George E. Abbott, Pasadena, vice-president; Dr. Charles G. Stivers, Los Angeles, secretary; Dr. Kate Wilde, Los Angeles, assistant secretary; and Dr. John C. Ferbert, Los Angeles, treasurer.

THE INDIANA ACADEMY OF SCIENCE held its sixteenth annual meeting at Indianapolis, in December. Dr. Robert Hessler, Logansport, read a paper in which he reviewed from the standpoint of the biologist questions connected with malarial fever. He then described the plasmodium malariæ, its life history and action on the human body.

THE COLLEGE OF PHYSICIANS OF PHILADELPHIA elected on January 2 the following officers: Dr. W. W. Keen, president; Dr. H. C. Wood, vice-president; Drs. W. F. Norris, R. A. Cleeman, A. V. Meigs and S. Weir Mitchell, censors; Dr. Thomas R. Neilson, secretary; Dr. R. H. Harte, treasurer; Drs. F. A. Taggart and E. J. Norris, councillors.

THE ERIE COUNTY MEDICAL ASSOCIATION held a meeting for organization December 20. This organization is in affiliation with the New York State Medical Association and THE AMERICAN MEDICAL ASSOCIATION. It will hold stated meetings four times a year. The following officers were elected: Dr. DeLancey Rochester, Buffalo, president; Dr. William H. Jackson, Springville, vice-president; Dr. Arthur G. Bennett, Buffalo, secretary, and Dr. Charles A. Wall, Buffalo, treasurer.

THE ST. LOUIS DISTRICT MEDICAL SOCIETY held a meeting at St. Louis, December 19 and 20. The report of the committee on legislation was read by Dr. Frank Tainter, Warrenton. A bill to regulate the practice of medicine in the state of Missouri, modeled after the New York state law, is ready and now being revised. It requires that all applicants for a license to practice medicine in Missouri pass an examination before the state board. No diploma will be recognized in lieu of the state board examination. The following officers were chosen: Dr. Frank J. Tainter, Warrenton, president; Dr. A. H. Ohmann-Dumesnil, St. Louis, secretary, and Dr. J. P. Dunigan, Sullivan, treasurer.

THE AMERICAN SOCIETY OF NATURALISTS held its nineteenth annual session in the different buildings of the Johns Hopkins University and Hospital, on Dec. 27 and 28. A large number of representatives of universities, colleges, biological and marine laboratories, health departments, etc., were in attendance. Among matters of medical interest are the following: Dr. Norman Harris demonstrated a hitherto undescribed pathogenic anaerobic bacillus, found in the case of a man who died of abscess of the liver. Dr. Ross G. Harrison showed a tail which had been removed from a child by surgical operation; this tail contained muscular fibers and could be moved by the child at will. Dr. L. K Hirschberg spoke of the distribution of the bacillus aerogenes capsulatus found in the stomach of man and other animals. Dr. Simon Flexner described his researches on the bacillus of dysentery. Dr. W. H. Park, of New York, spoke of the duration of typhoid bacilli in ice and showed that these organisms could live for two or three months in ice without losing their virulence. Drs. G. W. Fitz and F. W. Hutchings showed that the seasons have great influence on the weight and growth of children. There was a discussion regarding the establishment and publication of an American bacteriological journal, but no decision reached. Drs. G. A. Fried and W. J. Gies attempted to prove that the muscles of man and many animals contain mucin. Dr. E. C. Spitzka, of New York, read a paper on his studies of the brains of the two Drs. Sequin—father and son—both eminent neurologists and psychologists, and contrasted their anatomy. It was the first time the brains of such near relatives had been thus subjected to minute study and comparison, and the results were exceedingly interesting, particularly the selection of the opposite hemisphere in the son for traits inherited from the father. A discussion was held before a general meeting of all the societies on "The Attitude of the State Toward Scientific Investigation." Prof. W. T. Sedgwick was elected president of the American Society of Naturalists.

Western Surgical and Gynecological Society.

Tenth Annual Meeting, Minneapolis, Dec. 27 and 28, 1900.

President Dr. O. Beverly Campbell, St. Joseph, Mo., in the chair.

A brief address of welcome, on behalf of the local medical profession, was delivered by Dr. James E. Moore, which was responded to by Dr. A. C. Bernays, of St. Louis, Mo.

INSANITY IN WOMEN ASSOCIATED WITH PELVIC DISEASE.

DR. W. O. HENRY, Omaha, Neb., after briefly reviewing the current literature, stated that he believed a large majority of all insane women have some pelvic disturbance as an important, if not a chief, causative factor. He urged the bringing before the profession the testimony of all who had been giving this subject special study, so that the real truth might be arrived at. He reviewed briefly 16 cases from his own experience, of which 10 were cured mentally and physically; 3 were improved; 2 were no better, and 1 died. He held that these all might have been saved by earlier and more radical local measures. He drew the following deductions:

1. Many cases operated on, but not cured, have failed of relief, either because attention to the local disease was not given early enough, or was not sufficiently radical.

2. Every insane woman should be given the benefit of a thorough and painstaking pelvic examination, and all pelvic disturbances quickly cured as an essential element in permanent restoration of the mind.

3. In some cases, where lacerations have been repaired and endometritis cured, there still remains enough reflex trouble from the uterus and ovaries, not perceptible until their removal, to continue the mental disturbance and demand their entire removal.

4. The general practitioner, as well as the laity, should be more fully alive to the connection between pelvic and mental diseases in women.

5. Many cases of insanity in women would be wholly prevented if the pelvic lesions were easily repaired.

6. It is the duty of the profession, and especially of the general practitioner, into whose hands these cases first come, to urge on women the importance of keeping their procreative organs in absolute health, and of having all injuries repaired early, and diseases cured at once.

DR. C. H. MAYO, Rochester, Minn., followed with a paper entitled "Hypospadias," which will appear in THE JOURNAL.

present proportion being 1, 1 2/3, 8 1/3, and 20; the proposed proportion being 1, 2, 8 and 20. From this it will be seen that the proportionate rank in the number proposed in this section is within a fraction of the proportionate rank as it now exists in the Medical Department, and that, consequently, no injustice will be done the Medical Department by substituting the proposed numbers for those which now obtain. 3. The efficiency of the Medical Department depends upon the quality of the men who enter this department, and the quality of the men depends upon the inducements offered them to enter upon a life career in the military service. The efficiency of the Medical Department in the past has been maintained by the rank and pay secured by the grading of the officers, which now obtains, and this depends upon the relative number of officers in each grade. It has been shown that the relative number in each grade is practically similar in the proposed section to that which now obtains in the Medical Department. This proportion is much changed by S. 4300, for while the present proportion is 1, 1 2/3, 8 1/3, and 20, total 31, the proportion in S. 4300 is 1, 1½, 7½ and 30—a total of 40; while S. 4300 gives a slightly higher proportion in the higher grades it gives a much lower proportion in the lower grades, the difference in the lower grades being in proportion of 20 to 30, and if S. 4300 becomes a law the consequence will be that while officers in the upper grades will pass through these grades as rapidly as they did before, promotion for officers in the lower grades will be much slower. As at present constituted a majority in the Medical Department is reached after from 18 to 19 years' service, while if S. 4300 is adopted it will take over 25 years for an officer to reach the same grade. For this reason the adoption of S. 4300 could not but seriously impair the future efficiency of the corps, in that by materially reducing the emoluments, it would in the future offer too small an inducement to that class of professional men whose entry to the corps maintains its efficiency. It is believed that the adoption of the numbers in the section proposed will not only give the extreme minimum total number required for the Medical Department in time of peace, and the minimum number of officers of each grade necessary to perform the administrative work of the corps, but by giving practically the same proportion in each grade will enable the medical corps to maintain its present degree of efficiency, in that the same emoluments will be offered in the future as have been offered in the past. The continuance in service for a limited time of a certain number of volunteer surgeons is also recommended. This, for the reason that the exigencies of the service as they now exist in the Philippine Islands can not be met unless more medical officers are allowed than these give for the regular Medical Department. The exigencies of the service demand that these officers shall have the rank of major and colonel, as they have important and arduous duties to perform. Their period of service is limited, in that they are to be retained only so long as their services are necessary and in no case beyond two years after the passage of the act. The appointment of these officers serves a triple purpose in that it allows the retention in service of officers now holding important positions, allows a certain reward to those volunteer medical officers whose services have been of value in the past and gives them time and opportunity to prepare for the examination necessary for entry to the regular medical corps or to adjust their affairs prior to return to civil life. Another provision in the appended section follows the same lines. It provides that in emergency the President is authorized to appoint as many surgeons of volunteers with the rank of first lieutenant as may be necessary, subject to discharge whenever their services are no longer required. This proviso is important in that it allows the President to give an honorable title and position to contract surgeons of long service or special merit. This allows in large part the doing away with the contract surgeon system, using contract surgeons only for brief emergencies, and substituting for civilian quasi-officers a body of men who have the real military rank which is so necessary to a proper performance of the duties of a medical officer in the army. In no other staff corps or branch of the army are civilians employed to occupy the places and perform the duties properly belonging to commissioned officers, and medical men when occupying such positions in the army should have the rank to which their position entitles them and the efficient performance of their duties demands. The volunteer surgeons will act as "feeders" for the regular Medical Department in that their military training will stand them in good stead when they appear before an examining board should they desire to enter the regular medical corps; while, should they return to civil life, they will have the prestige of having been officers in the United States Army should they desire to do duty in the National Guard, or return to the service in time of war. Nor will the cost to the United States be thereby increased. A sufficient number of properly qualified surgeons can not be obtained unless commissions are offered, and every appointment of an inefficient surgeon is a source of expense to the government through the pension claims of his patients and their dependents. The proposed change will also result in large immediate economies to the government. A contract surgeon is not under military rules to the extent of a commissioned officer, and consequently he can and does leave the service before he has more than fairly learned his duties. This results in a constant change of personnel at a heavy direct cost for their pay and expenses while traveling, and also an indirect cost resulting from their military inexperience. The giving of commissions to these surgeons would not change their pay except that when serving in the United States it would be reduced about $300 a year. He urged the bringing before the profession the testimony of all who had been giving this subject special study, so that the real truth might be arrived at. He reviewed briefly 16 cases from his own experience, of which 10 were cured mentally and physically; 3 were improved; 2 were no better, and 1 died. He held that these all might have been saved by earlier and more radical local measures. He drew the following deductions:

1. Many cases operated on, but not cured, have failed of relief, either because attention to the local disease was not given early enough, or was not sufficiently radical.
2. Every insane woman should be given the benefit of a thorough and painstaking pelvic examination, and all pelvic disturbances quickly cured as an essential element in permanent restoration of the mind.
3. In some cases, where lacerations have been repaired and endometritis cured, there still remains enough reflex trouble from the uterus and ovaries, not perceptible until their removal, to continue the mental disturbance and demand their entire removal.
4. The general practitioner, as well as the laity, should be more fully alive to the connection between pelvic and mental diseases in women.
5. Many cases of insanity in women would be wholly prevented if the pelvic lesions were easily repaired.
6. It is the duty of the profession, and especially of the general practitioner, into whose hands these cases first come, to urge on women the importance of keeping their procreative organs in absolute health, and of having all injuries repaired early, and diseases cured at once.

DR. C. H. MAYO, Rochester, Minn., followed with a paper entitled "Hypospadias," which will appear in THE JOURNAL.

THE CHOICE OF OPERATIONS FOR STONE IN THE BLADDER.

Dr. Byron B. Davis, Omaha, said the best operation for stone in the bladder is one which the most nearly answers the following conditions: 1, has the lowest operative mortality; 2, is followed by the smallest percentage of recurrence, and 3, most nearly restores the urinary apparatus to a normal condition. The operation of lithotrity has a small mortality, chiefly because it is only used in the comparatively simple and uncomplicated cases. In the hands of lithotritists the serious cases are treated by one of the cutting operations, and of course their results show a large mortality. It is also shown that men who practice consistently the suprapubic method in all cases as they present themselves, have a mortality which bears comparison with the results of the most skilled lithoritists, The number of recurrences, when the cutting operations are practiced, followed by drainage, are few. Quoting from men with large experience, it is shown that after lithotrity, recurrences are very frequent, one in seven cases or oftener. In giving a reason for these numerous recurrences, the author finds that after lithotrity the conditions which lead to the formation of stone in the first place, are not removed by the operation of lithotrity. The condition most frequent is stagnation combined with the presence of micro-organisms. Furthermore, it is asserted that no man can be sure he has emptied the bladder of all fragments and particles of sand, and these, if left behind, will serve as nuclei for fresh stones. On the other hand, when drainage is used after a cutting operation, until all infection has passed away, one of the chief factors in the production of recurrence is eliminated. Through an incision, all fragments can be easily removed; if the prostate obstructs, it can be dealt with in such a manner as to insure complete emptying of the bladder in the future.

COCAINIZATION OF THE SPINAL CORD, ITS USE AND LIMITATION.

Dr. John B. Murphy, Chicago, read a paper on this subject. Analgesia is produced from the effect of the cocain upon the sensory roots and ganglia within the spinal cord. The affinity of cocain for the sensory nerve tracts was noted in the first experiments with this method. The speaker has been able to collect from recent literature 592 cases. Of this number, there were 4 partial failures, and 25 complete failures. Of the 592 cases there was only one death, this being partially attributed to the use of the drug, and was reported as having occurred in the clinic of Tuffier. Of the 5 deaths said to have occurrred in Tuffier's clinic, the first four patients died from other causes.

The dosage ranges from 1/20 to 1/10 of a grain for children. Even the 1/20 of a grain has been used in a child two and a half years of age. In adults the dose ranges from 1/6 to 1/2 a grain. In his personal work the speaker has not used more than 15 minims of a 2 per cent. solution. Usually he uses 12, many times 11, and very frequently 10 minims for operations on the cervix, the vagina, hemorrhoids, and for operations on the foot 10 minims is sufficient of the solution to use.

POST-OPERATIVE FISTULA.

Dr. J. R. Hollowbush, Rock Island, Ill., said that appendicular fistula may be external or internal; the material which escapes from the external type of fistula may be pus from an unhealed abscess cavity, or fecal matter from either the small or large intestine. The internal type of fistula is caused by the rupture of an abscess into one of the hollow viscera. The author reported cases of fistulæ following operations for appendicitis, biliary fistulæ, etc., and described a method of closing them.

CARCINOMA OF THE THYROID GLAND.

Dr. A. E. Halstead, Chicago, went exhaustively into the literature of the subject, saying that the study of primary carcinoma of the thyroid gland dated from a comparatively recent time. The results of operative treatment are not encouraging. Morris quotes Kuster concerning the outcome of 50 cases treated by complete or partial thyroidectomy. In 8, death followed within twenty-four hours after the operation; in 5, within a week; in 8, within two weeks. Four remained free from recurrence for six months. Only one was known to be well at the end of four years. In the cases not operated upon, death results in most instances within one and one-half years, either from suffocation, hemorrhage, thrombosis, or cachexia. In the cases reported by Poumet, Oser and Lebers, death resulted from rupture of the carotid artery. In the case of Franque the immediate cause of death was thrombosis extending from the internal jugular to the heart.

PATHOLOGY OF FRACTURES.

Dr. Lewis Schooler, Des Moines, Iowa, said that each case should be treated on its merits. The difference in the length and tension of muscles in the flexed and extended position of limbs is easily ascertained, and may be studied by any one. The difficulty with text-books and with legal requirements is a too strict adherence to former customs. These, in the eyes of the law, and of many surgeons, are wisely and firmly established. Experience, however, shows their difficulties and their inability to meet the requirements in many cases. Even physiological causes may intervene and cause delayed union, as in the case of pregnancy, etc.

TREATMENT OF FRACTURES OF THE NECK OF THE FEMUR.

Dr. John P. Lord, Omaha, is of opinion that no one method of treating these fractures can be adhered to, because various indications must be met. All are agreed in regard to the maintenance of efficient extension. It should be the aim of surgeons to reduce the deformity and to apply a dressing which will retain the fragments in constant apposition. The only exception to this dictum should be in those cases where extreme age or enfeeblement enforces relaxation of this vigilance. The writer will resort to Ollier's apparatus, or a modified Phelps' fixation appliance, as is done in orthopedic practice, when the next case presents its need, which will enable the attendants to place the patient in the upright position daily, or, as desired. Absolute fixation does not require so long a period of confinement as in the days of sandbags, with extension of equally uncertain efficiency.

OBSERVATIONS ON COMPOUND FRACTURES.

Dr. D. S. Fairchild, Clinton, Iowa, said these fractures come almost entirely under the head of emergency work and often occur under the most unfavorable circumstances. The prognosis of an open fracture depends on certain pathological conditions present, the chief of which is infection. The great majority of open fractures are made so by the traumatism which produces a solution in the continuity of the bone, or the fracture is made compound from within out by the sharp point of a fragment of bone when the opening may be very minute, or the fracture may be made an open one in a few days by the separation of a slough due to the devitalizing influence of an external contusion with consecutive pressure from within or from without, or both. Compound fractures caused by direct crushing violence are much more serious, in that the bloodvessels and nerves are liable to be involved, and the soft parts in general more seriously damaged.

AMBULATORY TREATMENT OF FRACTURES.

Dr. Frederick Rustin, Omaha, stated that in selected cases, confined principally to fractures of the fibula, Pott's fracture, fracture of the malleolus and tarsal bones, the ambulatory treatment is not only rational, but gives the patient the advantages claimed by this practice. Ambulatory treatment need not necessarily be immediate, but may be applied any time before the fragments are held in relatively firm position by the new growth which leads to the callus formation, so that a period of seven to fourteen days may elapse after the injury, and yet the ambulatory treatment may be applied. The advantages of the ambulatory treatment are: 1. The time which the patient saves, in some cases the period of incarceration being but a few days. 2. The swelling and edema are less, owing to muscular action, and there is less apt to be stiffness of the neighboring joints, less muscular atrophy, and union is apt to be hastened, owing to the fact that immobilization is not perfect, and irritation of the fragments stimulates a more hasty repair. The disadvantages are: the callus formation is much enlarged, owing to imperfect immobilization; embolic processes either of fat or blood are relatively encouraged; immobilization is insecure, owing to muscular action, and finally, non-union is not uncommon, particularly in people of advanced years.

The author does not advocate the ambulatory treatment in all fractures, but believes there are certain cases where it should be tried in justice to the patient.

TREATMENT OF FRACTURES OF THE SKULL.

Dr. James H. Dunn, Minneapolis, said the treatment of these fractures is essentially that of injuries to the cranial contents. Aside from the general management and care due to all serious head injuries, it consists of prevention of infection, the control of hemorrhage, removal of foreign bodies and displaced fragments, and the relief or prevention of irritating lesions of the cortex. The ends to be reached are generally understood, namely, to trephine in compound and depressed fractures, and to open the skull on the development of focal brain symptoms following suspected or recognized fracture, and under all circumstances to observe the utmost possible asepsis in the presence of an external wound or fissure of the base, and to avoid operative intervention in the absence of clear indications may be accepted as axiomatic. The X-ray is of no practical value except where metallic bodies were lodged within the skull.

Dr. C. C. Allison, Omaha, read a paper in which he discussed "Hernia of the bladder."

Dr. J. Clarence Webster, Chicago, read a paper on "Three Interesting Cases of Cesarian Section."

A CONSIDERATION OF THE DIFFERENT OPERATIVE PROCEDURES IN THE TREATMENT OF RETRODISPLACEMENTS OF THE UTERUS.

Dr. O. Beverly Campbell, St. Joseph, Mo., delivered the "President's Address," selecting the above for his subject.

In selecting a successful method of treatment for retrodisplacements of the uterus, it is necessary to note in each individual case of presence or absence of pathology in the adnexa, as well as the mobility of the organ. Adhesions between the uterus and rectum in retrodisplacements are invariably the result of pelvic inflammation, which will have usually produced pathological changes in the adnexa. The author classified retrodisplacements of the uterus. Operative treatment should not be resorted to until after reasonable trial of simpler methods of treatment. After mentioning the various methods of shortening the round ligaments, Dr. Campbell described one which he had devised himself. An anterior colpotomy after Martin's method is performed and the fundus is delivered into the vagina. Each round ligament in its turn is drawn out of its peritoneal covering through an incision near its uterine attachment and held with forceps. An incision is made anteriorly through the peritoneal coat of the uterus equidistant from the cornua and at a level with the attachment of the round ligaments. A pair of Spencer Wells' forceps is now passed beneath the peritoneal coat of the uterus and made to emerge at the uterine attachment of the round ligament. The drawn-out round ligament is fastened in the grasp of the forceps thus introduced, and drawn beneath the peritoneal coat of the uterus. The opposite ligament is treated in the same way. Chromicized catgut sutures, three in number to each ligament, are passed deep into the muscular tissue of the uterus and made to include the ligament. The rents in the peritoneal covering of the ligaments and uterus are closed with fine catgut sutures. In completing the operation after his method of treating the round ligaments, no attachment is made of the peritoneum. The vaginal wound is closed with chromicized catgut sutures. Convalescence after anterior colpotomy is very rapid. The majority of his cases are allowed to sit up out of bed the twelfth day after operation, and given the freedom of the halls the fourteenth day. This is certainly not the case where ventrofixation or Alexander's operation has been performed. His operation is applicable to both the vaginal and suprapubic routes.

Dr. F. Gregory Connell, Chicago, described a "New Intestinal Suture, with all the Knots Inside." See The Journal xxxv, p. 1151.

TRAUMATIC INJURIES OF THE URETER.

Dr. J. W. Macdonald, Minneapolis, stated that ureteral injuries were divided into: 1, subparietal injuries, or those in which no open wound communicates with the injured ureter; 2, penetrating wounds, or those in which an open wound communicates with the injured ureter; 3, surgical wounds, accidentally or intentionally inflicted.

The most common causes of rupture of the ureter were pointed out: and the symptoms, diagnosis, prognosis, and treatment dwelt upon. Dr. Macdonald reported a case, and presented the patient; a girl aged 9 years, who was dragged by a heavily loaded sled. Examination revealed a painful bruise on the right side. No hemorrhage from any internal organ occurred at the time of injury or subsequently. Patient improved rapidly for four days and was discharged. She was operated on three months afterward. The tissues were found infiltrated to a considerable extent with pus, and exposure of the ureter was rendered difficult and in some places impossible by necrotic and cicatricial tissues. The ureter was healthy for about three inches by the kidney, but here sloughing had taken place, and for several inches it was lost in a mass of cicatricial tissue. After a most tedious search, in which the writer opened into and closed the peritoneum at three different places, he considered further dissection was useless and removed the kidney. The patient made an uninterrupted recovery, and is now in excellent health.

ETIOLOGY AND PATHOLOGY OF SURGICAL INFECTIONS OF THE KIDNEYS AND OF THE CYSTONEPHROSES.

Dr. M. L. Harris, Chicago, considered the manner in which the microbes reached the kidneys; the concomitant conditions which favor the lodgement and development of microörganisms after they reach these organs, and the varieties of the microbe. He said there are four routes by which microbes may reach the kidneys, namely, through the blood-stream: along the urinary tract; through the lymphatics by contiguity, and directly from without by trauma. The pathologic changes, which vary according to the nature of the infecting microbe, were discussed, as well as the particular part of the kidney chiefly affected. Pyelitis, pyelonephritis, tuberculosis of the kidney, cystonephrosis, pyonephrosis, etc., were dwelt upon at considerable length.

Dr. W. H. Allport, Chicago, followed with remarks on the surgical infections and cystic enlargements of the kidney, their symptomatology and diagnosis.

TREATMENT OF SEPTIC INFECTIONS OF THE KIDNEYS AND CYSTONEPHROSES.

Dr. L. L. McArthur, Chicago, for convenience of consideration, subdivided the treatment into: 1, internal medication; 2, local applications (ureteral lavage and antiseptics); 3, surgical interference, either nephrostomy, or nephrectomy. Having determined the nature of the infection, by bacteriological examination, and the involvement of one or both kidneys, efforts should be made to remove the source of infection; to destroy or inhibit the organism in question, and to provide free exit to the products of infection. If the infection has been by extension from a corresponding cystitis, vigorous and systematic treatment of that must be at once instituted. The choice of medicaments is not of as much moment as the systematic carrying out of a rigid hygiene of the bladder. 1. If the urine be acid, especially so with the gonococcus and bacillus coli communis, to render the urine alkaline and ensure the elimination from the kidneys of much fluid. 2. Give some of the better antiseptics. Assist the kidneys by lightening their labors through good elimination from the bowels. As the bacillus coli communis is the most frequent cause of renal infection, it will be well to inhibit its multiplication in the intestinal antiseptics. 3. When, after a reasonable trial of these remedies, and the use of ureteral lavage *à la* Caspar, Albarran and Kelly, the case progresses unfavorably, as the majority perhaps will, there remains nephrostomy. Every renal operation which can be done without opening the peritoneal cavity is a safer operation, especially so with septic kidney; hence the selection of a retroperitoneal route.

Dr. J. E. Summers, Jr., Omaha, narrated a case of adenoma of the tongue.

Dr. Alexander Hugh Ferguson, Chicago, spoke of the various methods adopted by eminent surgeons for the excision of the superior maxilla, and then described a method which he had devised for removing the superior maxilla through the mouth.

THE CHOICE OF OPERATIONS FOR STONE IN THE BLADDER.

Dr. Byron B. Davis, Omaha, said the best operation for stone in the bladder is one which the most nearly answers the following conditions: 1, has the lowest operative mortality; 2, is followed by the smallest percentage of recurrence, and 3, most nearly restores the urinary apparatus to a normal condition. The operation of lithotrity has a small mortality, chiefly because it is only used in the comparatively simple and uncomplicated cases. In the hands of lithotritists the serious cases are treated by one of the cutting operations, and of course their results show a large mortality. It is also shown that men who practice consistently the suprapubic method in all cases as they present themselves, have a mortality which bears comparison with the results of the most skilled lithoritists, The number of recurrences, when the cutting operations are practiced, followed by drainage, are few. Quoting from men with large experience, it is shown that after lithotrity, recurrences are very frequent, one in seven cases or oftener. In giving a reason for these numerous recurrences, the author finds that after lithotrity the conditions which lead to the formation of stone in the first place, are not removed by the operation of lithotrity. The condition most frequent is stagnation combined with the presence of micro-organisms. Furthermore, it is asserted that no man can be sure he has emptied the bladder of all fragments and particles of sand, and these, if left behind, will serve as nuclei for fresh stones. On the other hand, when drainage is used after a cutting operation, until all infection has passed away, one of the chief factors in the production of recurrence is eliminated. Through an incision, all fragments can be easily removed; if the prostate obstructs, it can be dealt with in such a manner as to insure complete emptying of the bladder in the future.

COCAINIZATION OF THE SPINAL CORD, ITS USE AND LIMITATION.

Dr. John B. Murphy, Chicago, read a paper on this subject. Analgesia is produced from the effect of the cocain upon the sensory roots and ganglia within the spinal cord. The affinity of cocain for the sensory nerve tracts was noted in the first experiments with this method. The speaker has been able to collect from recent literature 592 cases. Of this number, there were 4 partial failures, and 25 complete failures. Of the 592 cases there was only one death, this being partially attributed to the use of the drug, and was reported as having occurred in the clinic of Tuffier. Of the 5 deaths said to have occurrred in Tuffier's clinic, the first four patients died from other causes.

Every renal operation which can be done without opening the peritoneal cavity is a safer operation, especially so with septic kidney: hence the selection of a retroperitoneal route.

Dr. J. E. Summers, Jr., Omaha, narrated a case of adenoma of the tongue.

Dr. Alexander Hugh Ferguson, Chicago, spoke of the various methods adopted by eminent surgeons for the excision of the superior maxilla, and then described a method which he had devised for removing the superior maxilla through the mouth.

OPERATIVE MANAGEMENT OF RETROPERITONEAL ABSCESS OF APPENDICULAR ORIGIN.

Dr. Gilbert G. Cottam, of Rock Rapids, Iowa, read a paper with this title in which he gave the following explanations of the occurrence of retroperitoneal abscess of appendicular origin: 1. Inflammatory attachment of the tip of the appendix to either fold of the mesocolon, followed by perforation into the post-colonic space. 2. Transmission of the infection from an acutely inflamed appendix, situated anteriorly, along the lymphatics of the appendix and cecum to the mesocolic glands. 3. Abnormalities of the peritoneal investment of the appendix. In about 75 per cent. of cases the meso-appendix is lacking, rendering the appendix an extraperitoneal organ, in contact with the peritoneum only on its anterior aspect. This type may be termed the retroperitoneal appendix and demonstrates its proximal relations to the postcolonic space. The various procedures available for reaching, evacuating and draining retroperitoneal abscesses were given. After treating all of these in detail and describing illustrative cases, the author concluded by advocating the posterior incision in all cases where a retroperitoneal abscess is suspected, or where there is doubt as to whether the abscess is in front of or behind the posterior parietal peritoneum, for the following reasons: It does not open the general peritoneum; it allows drainage by gravity; it disposes of the hernia problem, and if the abscess should prove to be anterior, the iliac incision can still be used and drainage instituted through both openings, the lumbar incision then corresponding to the counter-incision as now ordinarily used.

ANATOMICAL AND SURGICAL OBSERVATIONS ON APPENDICULAR ABSCESS.

Dr. A. C. Bernays, St. Louis, said that the earliest operation of appendectomy in which he has found pus in the cavity of Douglas was done on the morning of the third day, about fifty hours after the attack, and the amount of pus was over a pint. The large majority of cases were operated between the eighth and fifteenth days, i. e., during the second week. He believes the most reliable sign of Douglas' abscess is the appearance of abdominal distension early in an attack of appendicitis. The drainage per rectum in men and per vaginam in women of typical Douglas' abscesses is an easy and successful treatment in uncomplicated cases. In cases in which Douglas' abscess is complicated by iliac, lumbar, or some other abscesses, or in which the Douglas abscess reaches so high, that it can be felt above Poupart's ligament, it has often been opened and drained from the anterior abdominal parietes.

Dr. Van Buren Knott, Sioux City, Iowa, gave a further report of a case of cerebral cyst on which he had operated some three and a half years ago.

OPERATIVE MANAGEMENT OF HIP-JOINT DISEASES: A CRITIQUE.

Dr. A. F. Jonas, Omaha, drew the following conclusions: 1. The aim of the surgeons should be radical in the removal of all affected structures and the preservation of all healthy bone. 2. To preserve the greatest amount of healthy bone and consequently to insure the best possible joint function, makes early incision imperative. 3. To insure the best possible function means not only the early evacuation of intra-articular tubercular products, and the removal of diseased structures, but implies a most thorough disinfection. 4. The most effective disinfection method known at the present time is pure carbolic acid and alcohol. 5. To insure the retention of the femoral extremity in the cotyloid cavity, which is necessary to insure good function, requires the greatest possible obliquity of the upper end of the bone. This can be done only by preserving as much of the neck as possible. Where a portion of the neck is destroyed or must be removed, a certain obliquity can be obtained by removal of the trochanter major. 6. To insure permanent usefulness of the hip-joint, long-continued mechanical correction by means of portable extension brace must be insisted upon. 7. Excision of femoral head, neck and trochanter must be avoided when possible.

SYMPOSIUM ON SURGICAL TUBERCULOSIS.

Dr. J. Clark Stewart, Minneapolis, discussed tuberculosis the fascia; Dr. Rollin E. Cutts, Minneapolis, tuberculosis of tubes, ovaries and peritoneum, and Dr. Knute Hoegh, Minneapolis, tuberculosis of bones and joints.

TREATMENT OF TUBERCULOSIS OF BONES AND JOINTS.

Dr. James E. Moore, Minneapolis, said the treatment of tuberculosis of bones and joints is almost inseparable because the disease usually begins in the epiphysis of long bones and the neighboring joint soon becomes affected. Tuberculosis of the shaft of long bones is so rare that some surgeons have never seen a case. When it does occur, the only treatment to be considered is the complete removal with hammer and chisel, and in the absence of a mixed infection allowing the wound to fill with blood-clots. Bone chips, iodoform, and boracic acid are not as good as the blood-clot. Orthopedists have arrived at great perfection in their methods and know just about what they can accomplish, but they are too well content with their methods and do not resort to operative measures soon enough. Their results are slow and unsatisfactory, but are better than the surgeon can offer at present.

Every case of joint tuberculosis is best treated for a short time by rest in bed, with extension by weight and pulley. An apparatus applied later should afford rest and protection to the joint, and should hold the limb in proper position, since a tubercular joint once cured in a faulty position can not be broken up safely. Plaster of Paris will yield better results in inexperienced hands than complicated braces. It should be applied just tight enough, not too heavy, and should extend far enough above and below the joint to prevent motion. When joints of the lower limbs are affected, crutches with a high shoe on the well foot should supplement the plaster bandage. The injection method of treatment is not recommended. When a joint is growing worse, in spite of good mechanical treatment, it should be operated on without delay. Pure carbolic acid and the actual cautery are recommended as valuable aids in operative cases. Whether the disease be primary or secondary, it can be cured by complete removal. The surgeon should be as careful to remove all diseased tissue as if he were operating upon malignant disease.

TOPICAL APPLICATIONS IN GYNECOLOGICAL PRACTICE; THEIR USE AND ABUSE.

Dr. J. W. Andrews, Mankato, Minn., expressed himself as having very little confidence in the utility of pessaries, and in topical applications in gynecological practice. In a large majority of cases of retroversion or retroflexion of the uterus with tenderness in Douglas' pouch, he believes there is some disease of the ovaries and tubes on one or both sides, and this can only be cured by surgical measures. In concluding his paper he expressed the belief that there is no longer a legitimate field for the gynecologist. There is no reason why a good surgeon who can operate well on the abdominal organs should not operate equally well on the pelvic organs. There is no reason why the general practitioner can not treat catarrh of the cervix, when it exists, as well as he can a catarrh of the throat. He hoped that the routine topical applications in gynecological practice would be relegated to the mistakes of the nineteenth century.

A CALCAREOUS UTERINE FIBROMA.

Dr. H. G. Wetherhill, Denver, reported a fibroid tumor of the uterus, one nodule of which had undergone complete calcareous degeneration. The tumor was a true fibromyoma in all its parts, except this particular nodule, which was quite symmetrical, entirely interstitial, and so infiltrated with lime salts as to appear like a mass of uncalcined limestone, and so dense as to require the use of a bone saw for making a section. Its diameters were 4 and 3 inches. The clinical history of the patient was like that of others with fibroid tumor, except for a notable record as to cancer. Her father, mother, two maternal aunts and one paternal aunt had died of that disease. Patient recovered from the operation.

FIBROMYOMA OF THE URETHRA.

Dr. Wetherhill also reported an operation for the removal of a tumor of the urethra and anterior vaginal wall, the tumor being a myofibroma and having its origin in the muscular coats of the urethra and completely enveloping that canal. The tumor was 3½ inches long by 2 inches wide, and was first noticed twenty years before removal. It was reducible, but was not retained within the vagina unless resort to packing was had. The specimen is interesting chiefly on account of its rarity, the only other myoma of the urethra found reported by the author being one quoted in Kelly's "Operative Gynecology." Examination of the tumor by a pathologist showed it to consist almost entirely of fibrous tissue, a few unstriped muscular fibers being scattered through the tumor.

The following officers were elected for the ensuing year: President, Dr. A. F. Jonas, Omaha; vice-presidents, Dr. A. W. Abbott, Minneapolis, and Dr. C. E. Ruth, Keokuk, Iowa; secretary-treasurer, Dr. George H. Simmons, Chicago; executive council, Drs. O. B. Campbell, St. Joseph, Mo.; H. C. Crowell, Kansas City, Mo.; John P. Lord, Omaha; James E. Moore, Minneapolis, and M. L. Harris, Chicago. Next place of meeting, Chicago. Chairman of committee of arrangements, Dr. John B. Murphy.

California Academy of Medicine.

Monthly Meeting, Nov. 27, 1900.

Dr. W. W. Montgomery in the chair.

LEPROSY.

Dr. Howard Morrow exhibited a man aged 50, suffering from leprosy. He was born in Germany, but for the past fifteen years had lived in the Hawaiian Islands. He roomed with a male leper for one year in Honolulu. Six months ago he noticed a white area on the ulnar side of the wrist of the right hand, with slight traction of the little finger and shooting pains in it. Four months ago several brownish-red nodules developed on this whitened area, and others appeared in the skin on the back of the left hand, two on the forearm, one on the shoulder, two on the abdomen, and one on the right thigh. The nodules on the hand were confluent and anesthetic to pain, heat, and touch. Other nodules were seen, slightly indistinct. The case was of interest, because no bacilli had been demonstrated on sections taken from the nodule on the shoulder, also because there was no fever with the development of the nodules, and from the fact that no nodules had developed since the patient came to this country two months ago. Histological examination showed areas of plasma-cell infiltration in the corium, and a few larger cells, probably "lepra cells," but no bacilli could be found in them.

Dr. D. W. Montgomery said this case was particularly interesting on account of its resemblance to either leprosy or syphilis. When he first saw the case he had thought it was syphilis, but the anesthesia threw doubt on such a diagnosis. He found some places on the body where he had expected to find lepra bacilli, but they were not found. Dr. Morrow did find some bacilli which stained with methylene blue, were grouped, and resembled very much the lepra bacillus. These bacilli were very short. The fact of there being anesthetic areas over several of the infiltrations, and of his coming from a leprous country, and living with a leper, certainly pointed to a diagnosis of leprosy. He was put on syphilitic treatment simply because no lepra bacilli were found, and not because results were really expected from such treatment. There were some points also in the histology which pointed to leprosy and not to syphilis.

CARCINOMA OF STOMACH AND PYLORUS.

Dr. T. W. Huntington exhibited a case with the following history. A man aged 65, native of Ireland, entered the City and County Hospital about Aug. 1, 1899. For the past year his health had gradually failed; he had suffered from pain in epigastrium, anorexia, occasional emesis, constipation, and gradual loss of weight. On entrance he was very weak, refused solid food, and would take only limited quantities of milk. He was pale, anemic and cachectic. Pressure below ensiform cartilage elicited pain. Examination of stomach contents showed absence of hydrochloric and excess of lactic acid. Stomach was greatly dilated. Diagnosis was carcinoma at or near pylorus. Operation took place Aug. 5, 1900. Median line incision was made below ensiform cartilage. Upon exposing pyloric end of stomach there was discovered an induration occupying the pylorus and extending along lesser curvature of stomach for four or five inches. The upper part of duodenum was thickened but not distinctly indurated; adjacent organs free from metastases. The upper portion of the duodenum, the pylorus and lower segment of stomach were removed. The stomach was closed by a double row of Lembert sutures, and the upper end of duodenum was attached to posterior wall of stomach by a Murphy button. The parietal wound, owing to exhausted condition of patient, was hastily closed by through-and-through silkworm-gut sutures. For five days the patient was fed per rectum. After that time food was given in small amount by the mouth. The patient made a fairly quick recovery, and the button was recovered on the thirteenth day. Prof. A. E. Taylor reported the specimen to be one of carcinoma of stomach and pylorus. There were evidences of malignancy at or near the upper margin of the stomach wall. After the first three weeks solid food was ingested and digested with comfort. He gained weight and strength slowly; was free from pain; appetite was good. On October 1, the supraclavicular glands were found to be enlarged and indurated. At the present time the glands above noted are apparent, but not so large as when first observed. There is a well-marked ventral hernia at site of incision. Patient's appetite remains good and digestion excellent. There is a suspicious feeling of resistance below ensiform cartilage, but no tenderness, and the inference is that if there be a recurrence of the growth in the stomach wall, it is remote from the anastomotic orifice, and non-obstructive. He is able to be about and seems to enjoy an altogether comfortable existence. The ventral hernia will be repaired in the near future and the case carefully watched with reference to final outcome.

Dr. Dudley Tait said there were several interesting features in Dr. Huntington's case. The extent of the involved area was remarkable. He had never seen a pyloric growth extending in the direction of the duodenum. In one specimen of pyloric cancer seen at the dead table, he noted an infiltration of the submucosa of the duodenum. The serous and mucous layers were apparently intact. The usual ocular inspection in an operation on such a case would have proved useless. In a growth like that described by Dr. Huntington, involving one-third of the duodenum the pylorus and a portion of the stomach, one would expect to find several glands, especially in the retropyloric region. All operations are useless unless these glands are completely removed. The supraclavicular glands found in carcinoma of the abdominal viscera are not always malignant. In two cases of cancer of the stomach, under observation at the French Hospital, Dr. Tait had removed a large gland from the neck, which proved to be tuberculous. In both of these cases all radical measures had been considered useless on account of the presence of the enlarged supraclavicular glands.

Dr. Huntington said that he had been in doubt regarding the condition of the duodenum, and removed a portion of it because it looked suspicious. He was aware that it was not usually involved. The retropyloric glands seemed normal, though no doubt if he had gone up the lesser curvature to the cardiac orifice he would have found some enlarged. The patient improved wonderfully after the operation. He now ingests and digests food well, and gains in strength. While he thinks he did not remove enough of the stomach, the operation has certainly been justified by the comfort of the patient following it. Recurrence, if there had been any, had been through the glandular system.

MYXEDEMA.

Dr. Herbert C. Moffitt reported three cases of myxedema in children, and exhibited two of the patients before the academy.

Dr. T. W. Huntington said that some years ago he had removed an entire thyroid and the patient had developed myxedema within a year. He is a bookkeeper, holds a responsible position in Sacramento, and remains in very good condition, but has to resort to thyroid treatment for about a month at a time three or four times a year. He had not seen him now for several years, but understands he is living a useful life.

Dr. Wm. W. Kerr, in discussing the treatment with the thyroid extract, said that the dosage necessarily varies and depends largely on what preparation is used. A patient he had was taking 15 grains a day of the preparation of a certain manufacturer. This patient went east and was referred to Starr, who put him on an English preparation, and he improved remarkably on 5 grains, first twice, and then once a day. Another patient takes 5 grains of this preparation once a week. He had consulted cattlemen for an explanation as to this difference in American and English preparations, and believed it is due to the fact that in this country the thyroid gland in the sheep atrophies after the first year. Regarding the duration of the treatment, if the gland has been removed, or there is deficient secretion, the patient will always have to use the extract.

Philadelphia County Medical Society.

Meeting Nov. 28, 1900.

Dr. George Erety Shoemaker, in the chair.

CUTANEOUS SYPHILIS.

Dr. Jay F. Schamberg reported a case of refractory cutaneous syphilis and exhibited the patient, a woman aged 39 years, who had, in 1892, been inoculated with syphilis, the disease having been contracted from her husband. Later a number of reddish and elevated rounded patches appeared on the arms and legs. A large reddish scar also existed in the palmar surface of the right hand, and painful paronychia was also present on one of the digits. The patient had gained in weight during the past year. One physician had given hypodermics of bichlorid together with mercurial inunctions. She had lately been taking iodids, but without much benefit.

Dr. M. B. Hartzell stated that in many of these cases he had seen good follow the administration of the potassium iodid in very large doses and he had in one instance given as much as half an ounce daily.

TREATMENT OF GONORRHEA.

Dr. Edward Martin spoke on the treatment of gonorrhea. His remarks were confined to the line of treatment which he had found most efficacious during the past few years. The results had been compared with that obtained in the treatment of about 80 cases of the old plans of treatment. Of these 80 cases some had taken in the late stages of the disease, oil of cubebs, oil of sandalwood, and oleoresin copaiba. He had found that oil of cubebs was practically useless; salol, oil of sandalwood and copaiba did good. A combination of salol, oil of sandalwood and copaiba was best for internal use. Some patients had been for a time treated on the expectant plan, and the results had not been good. His present plan of treatment is as follows: When the case is first seen, if it be within the first few hours, or first twenty-four hours from the onset of the symptoms, the patient is to use an injection of a solution of protargol 6 grains to 3 ounces every two or three hours during the day. Before inserting the rubber nozzle in the meatus one or two drops of the solution should be dropped on the parts so as to wash away any debris or septic material. The rubber nozzle should then be inserted and the fluid injected and retained in the usual manner for about three minutes. On the following day the urethra should be irrigated with a solution of potassium permanganate 1 in 6000. The fluid should be placed in a fountain syringe and the parts irrigated daily by means of a short—about half an inch—blunt hard rubber nozzle made to fit the parts. About one and a half pints of the fluid should be used. After a few days the permanganate and protargol solutions might be increased in strength. Internally salol and lithium citrate might be given. Each night a prolonged hot bath should be given, since this tends to lessen the amount of congestion, and prevents priapism. He had frequently been able to cure patients of gonorrhea by this method within fifteen days. It should however be remembered that there are some cases refractory to every line of treatment. After six weeks a bougie or dilatable urethrotome might be used to determine the tender spots which might receive local treatment. He had lately almost discarded the use of the cystoscope in the treatment of gonorrhea.

Dr. Heller Christian stated that the protargol solution was the best drug he had tried in the treatment of gonorrhea. He used a solution of protargol 10 grains to 4 ounces; and a solution of potassium permanganate ½ grain to 8 ounces. He believed the protargol solution should be retained as long as fifteen minutes, since it required this length of time to obtain the best local effect. About the second week the strength of the medicines should be doubled. About the fourth week copaiba and sandalwood oil should be given. He believed most failures had resulted from the fact that physicians had not determined whether the disease had been an anterior or posterior one. If posterior urethritis existed irrigation should be done every day. The diagnosis could be told by having the patient first urinate in one glass and the latter portion in another similar vessel. The part showing the mucus or sediment would give the clue. In chronic gonorrhea or when the prostate is involved, massage of this organ should be done through the rectum.

CYSTOSCOPY IN WOMEN.

Dr. John G. Clark spoke on this subject and exhibited the instruments necessary. The speaker stated that when abroad he had observed that in many of the clinics the operators did not seem to be familiar with all the technique of carrying out cystoscopy as practiced by Howard Kelly. In one clinic a failure had resulted from the fact that the operator had placed the patient in the Sims position instead of the knee-chest posture. The latter position is always necessary, since the bladder is drawn forward, and is dilated more on account of the atmospheric pressure. In cystitis it should be remembered that the inflammation is not usually diffused over the entire organ. As a rule the part most affected is simply the vesical trigone. The diagnosis is best made by the Nitze instrument, and the treatment by the Kelly urethroscope of the later pattern, which gives a better view of the field.

Dr. B. Alexander Randall offered a resolution that it was the sense of the Society that the best interests demanded the payment by the Board of Education of a salary ($500) to each medical inspector (100) of the public schools. Carried unanimously.

New York Academy of Medicine.

Section on Obstetrics and Gynecology, Nov. 22, 1900.

ABDOMINAL VERSUS VAGINAL HYSTERECTOMY FOR CANCER OF THE UTERUS.

Dr. William R. Pryor, in opening the discussion on this subject, said that a successful operation for cancer of the uterus must comprise the removal of the uterus, the adnexa, a considerable portion of the vagina, and certain glands. The most important of the latter, in this connection, were the obturator, though perhaps the most commonly overlooked. Other glands requiring attention were those at the bifurcation of the common iliac and those at the uterosacral folds. Vaginal hysterectomy was, of necessity, only an incomplete operation for uterine cancer, except in a few cases. Statistics from abroad, founded on 3155 vaginal operations, gave a mortality of 9 per cent.; his own collation of American statistics gave the mortality from the abdominal operation as 11.8 per cent. A fundamental principle in these cases should be, that in the removal all possibility of infecting the wound with either cancer cells or with the very septic contents of a cancerous uterus must be avoided. Another principle was that as little violence should be inflicted on the growth and the surrounding structures at the operation. While the vaginal operation was preferable as a purely palliative measure, he believed that the abdominal operation alone met the requirements for the radical operation.

Dr. H. J. Boldt said that, in the present state of our knowledge, he thought it was only exceptionally that abdominal hysterectomy should be done for uterine cancer. Vaginal hysterectomy allows of a smaller opening of the peritoneal cavity, takes less time to perform and is followed by a much more rapid convalescence; moreover, there was no abdominal wound with its occasional bad consequences. The one advantage of the abdominal operation was the opportunity it afforded for extensive removal of infected glands, yet it was now generally conceded that the blood-vessels and glands were often not involved until late in the disease.

DR. J. E. JANVRIN stated that, looking back 18 years, he could point with pleasure to fully one-third of his operative cases of uterine cancer as having been permanently cured. Of course, it was only in very early cases that such results could be expected, yet he was in favor of operating in even advanced cases, as he was of the opinion that the patient was made more comfortable thereby.

DR. WILLIAM M. POLK said that while preferring the abdominal route he could only look on these cases with horror, as only one of his cases had survived without recurrence.

DR. W. GILL WYLIE said that in cases occurring in older women it was possible by an early and radical operation to effect many cures. It was most important that an interval of several weeks should not be allowed to elapse between the removal of a fragment of tissue for examination and the performance of the radical operation, should the diagnosis justify such a course.

DR. RAMSAY, of Yale, thought the surgeon should not adhere to one operation for all cases of uterine cancer. He preferred the suprapubic method for most cases, but was inclined to think that the operation of the future would be the combined method.

DR. A. PALMER DUDLEY heartily endorsed the view that the combined method was the best of all.

Therapeutics.

Exophthalmic Goiter.

M. A. Starr, in *Med. News*, advises rest, careful diet, mercury inunctions to the neck, especially the red iodid of mercury, tincture of iodin—minims five three times a day—and belladonna, are sometimes of use. The use of iron and arsenic as blood-builders are of use. Injections of iodin and other irritants are dangerous. Digitalis, strophanthus and counterirritation are of little benefit, when there are pressure symptoms partial extirpation must be performed. He administers sodium glycerophosphate to counteract the poison in the blood:

R.	Sodii glycerophosphati	℥i	32

M. Ft. chartulæ No. xxxii. Sig. One powder after each meal in water.

This preparation is miscible in water and is of use in all cases where the system needs phosphorus. It can be given hypodermically.

Treatment of Compound Fractures.

Dr. S. Leigh, in the *Southern Medical Journal*, emphasizes the following important points in the treatment of compound fractures:

1. Free opening of the wound.
2. Removal of all useless torn tissues.
3. Thorough disinfection.
4. Good coaptation of bones.
5. Loose closing of the wound.
6. Firm pressure dressing.
7. Constitutional treatment.

He places special stress on the constitutional treatment, so that the tissues, both soft and bony, will unite quickly and thoroughly—such as good food, plenty of pure water, mild cathartics, strong doses of strychnin and iron with cod-liver oil, iodids in appropriate cases, and lime in the form of syrup lactophosphate.

Chronic Bronchitis.

R.	Eucalyptol	ʒi	4
	Tinct. opii camph......................	ʒiv	16
	Syr. tolutani	℥i	32
	Syr. simplicis, q. s. ad	℥iv	128

M. Sig. One teaspoonful every four hours.

Association of Trional and Paraldehyde.

According to the *Phila. Med Journal*, Rapiteau states that trional is freely soluble in paraldehyde and that the mixture is four or five times as active as trional alone when used as a hypnotic. He recommends, in *Thése de Paris*, the following formulæ:

℞.	Trional	gr. xv	1
	Paraldehyde	gr. xxx	2
	Ol. amygdalæ dulcis	ʒiv	16

M. Sig. At one dose.

AS AN ENEMA.

R.	Trional,		
	Paraldehyde, āā..................	ʒss	2
	Yolk of one egg,		
	Lactis	℥iv	128

M. Sig. Use in the form of an enema.

AS A SUPPOSITORY.

R.	Trional	gr. iii	2
	Paraldehyde	gr. viss	4
	Olei theobromatis	ʒi	4

M. Sig. Use as a suppository.

For the Pains in Tabes Dorsalis.

R.	Phenacetini	gr. xx	1
	Caffeinæ citratæ	gr. x	66
	Salol	gr. x	66
	Acetanilidi	gr. xv	1
	Sodii bicarb	gr. x	66

M. Ft. capsulæ No. x. Sig. One capsule every three hours until the pain is relieved.

[Phenacetin and acetanilid act particularly upon the spinal cord and its sensory tracts, and consequently can take the place of the opium preparations a great many times in relieving patients subject to these attacks].

Ohlemann, in *Ocular Therapeutics*, gives the following formulæ for local applications when indicated in diseases of the eyelids, such as styes, etc.:

R.	Hydrarg. chloridi corros..........	gr. 3/20	01
	Vaselini	℥i	32

M. fiat unguentum. Sig. As an ointment to the eyelids.

℞.	Sulphuris sublim..................	gr. xlv	3
	Ammon. chloridi	gr. xv	1
	Aquæ rosæ	℥iss	48
	Spts. camphoræ	ʒiss	6

M. Sig. For local use on the lids.

℞.	Hydrarg. oxidi flavi	gr. iss	1
	Lanolini	℥iss	48
	Glycerini, q. s.		

M. Ft. unguentum. Sig. As an ointment for the eye.

Treatment of Abortion.

H. B. Stehman, in *Medicine*, states the following principles in treatment of abortion and its complications:

1. The rendering of the vulva, vagina, and uterus aseptic and as far as possible maintaining them in that condition.

2. Arresting hemorrhage, either by the use of the tampon in the cervix or vagina, or by directly emptying the uterus.

3. In inevitable abortion, the ovum, or any part of the product of conception should be removed as early as possible.

4. That intelligent curettage is invariably indicated whenever a vestige of placental decidua remains or any suspicion of infection is evident and that a bacteriologic differentiation is necessary both from the standpoint of prognosis and treatment.

5. When circumscribed local infection is a complication, evacuate the pus as early as possible and by the shortest route.

Psoriasis.

Dublitz, in *Jour. de Med. de Paris*, recommends the following:

℞.	Olei cadini—cade	ʒii	8
	Zinci oxidi	ʒiii	12
	Vaselini	℥i	32

M. Sig. For local application.

Chronic Ulcers of the Leg.

In the *Trained Nurse*, L. B. Fisher outlines the method of dealing with chronic ulcers which had been developing for several years and have never entirely healed during the time.

1. Use aseptic methods, as for any wound.
2. Spray with hydrogen peroxid thoroughly.
3. Make the ulcers perfectly dry with absorbent cotton.
4. Dust with acetanilid, one part mixed with boracic acid four parts.
5. Use strips of dry antiseptic gauze, an inch wide and a yard long over each ulcer. Lay them on loosely so as to be effective absorbents.
6. Place antiseptic cotton on top of the gauze.
7. Bandage from toes to knee with firm cotton bandage.
8. Bandage with a starch bandage when the patient is inclined to meddle with the bandage.

When the ulcer is deep, cut a disc of pasteboard large enough to extend half an inch beyond the edge of the ulcer and cut a hole a little smaller than the ulcer in the center of the disc. Bandage this over the ulcer. This will aid granulations.

Powdered charcoal should be used on ulcers that are gangrenous before using the acetanilid mixture. The legs must be freed from dead cuticle by use of alcohol.

Palatable Expectorants for Children.

H. B. Sheffield states that creosote is of great value in protracted coughs, and prescribes it in the following manner:

℞.	Creosoti—beechwood	gtt. viii-xvi		5
	Glycerini	ʒiv	16	
	Vini xerici, q. s. ad	℥ii	64	

M. Sig. One teaspoonful as necessary.

He also enumerates other expectorants which are palatable, such as liq. ammonii anisat., syr. scillæ comp., vinum ipecacuanhæ, syrupus senegæ, tinct. cubebæ, mistura glycyrrhizæ comp.—Brown's mixture—syrupus pruni virginianæ, syrupus tolutani, syrupus altheæ; the last four are also excellent adjuvants.

Frostbite—Congelatio.

Allen Gihon, in the "Twentieth Century Practice of Medicine," states that the proper course of treatment is to endeavor to restore the circulation. If the part which is frozen is exposed to high temperature before the circulation is restored, its death will necessarily follow.

For the purpose of restoring the circulation ice, snow or iced water, which may be gradually raised in temperature, must be depended on. The patient should not be placed in a warm room or brought near a fire until the normal circulation is established; otherwise the inflammation may end in gangrene.

FOR LOCAL APPLICATION.

A local application, which seems to do most good is:

℞.	Ichthyoli	ʒii	8
	Lanolini	ʒvi	24

M. Sig. Local application as necessary.

Gihon states that this ointment almost immediately relieves the pain.

FOR RAW FROSTBITES.

When the parts become raw and exposed, the following has been found of service:

℞.	Acetanilidi	gr. xlviii	3	20
	Lanolini, q. s. ad	℥i	32	

M. Sig. Apply locally.

When ulceration occurs, his statistics show that the acetanilid ointment will best prevent suppuration and promote granulation and cicatrization. When sloughing occurs treat same as when due to other causes—by warm boric-acid dressings, hot fomentations.

FOR MILD FROSTBITES.

In the treatment of the milder forms of frostbite rub the part well with snow or ice-water and afterward apply iodin, of which the tincture or compound tincture is most frequently used:

℞.	Argenti nitratis	gr. v		33
	Aquæ destil	℥i	32	

M. Sig. Paint the affected part frequently with this solution and then wrap the part in raw cotton.

Solutions containing resorcin, tannic acid, carbolic acid and camphor have been used with benefit.

The following is recommended by Boeck:

℞.	Ichthyoli		
	Resorcin		
	Acidi tannici, āā	ʒi	4
	Aquæ	ʒv	20

M. Sig. Apply with a brush at night.

As a rule, iodin should be used only when the skin remains unbroken:

℞.	Tinct. iodi	℥ss	16

Sig. Apply with a brush once or twice daily; or:

℞.	Ichthyoli	ʒiii	12
	Olei terebinthinæ	ʒi	4
	Adipis lanæ hydrosi, q. s. ad	℥ii	64

M. Sig. Spread on a piece of sterilized gauze and apply when the skin remains unbroken.

Hydrous wool fat is a yellowish white unctuous mass, containing about 25 per cent. of water. It freely takes up water and aqueous solutions. It is emollient and serves well as a base for ointments.

SOZOIODOLE-POTASSIUM IN FROSTBITES.

Sozoiodole-potassium is deserving of its reputation in frostbites as in other skin troubles. It should be prescribed in the following form:

℞.	Sozoiodole-potassii	ʒii	8
	Lanolini, q. s.	℥i	32

M. Ft. unguentum. Sig. For local application.

[Sozoiodole is a white, odorless, crystalline powder, containing:

Iodin	52.8	per cent.
Phenol	20	per cent.
Sulphur	7	per cent.

and is usually prescribed in ointments of 10 to 25 per cent. strength.]

ULCERATED FROSTBITES.

Bulkley has used the following on frosted fingers and toes with ulceration with good results:

℞.	Acidi carbol	gr. xx	1	33
	Vaselini	℥i	32	

M. Sig. Apply locally.

The pain will quickly subside and rapid healing will follow.

Lassar, in "Handbook of Local Therapy," gives the following:

℞.	*Acidi carbol*	*gr. xvss*	1	
	Unguenti plumbi			
	Lanolini, āā	ʒv	20	
	Ol. amygdalæ	ʒiiss	10	
	Ol. lavendulæ	gtt. xx	1	33

M. Sig. For local application.

THIOL.

Dillon, *Am. Jour. Med. Sci.*, states that thiol, which is practically an artificial ichthyol, differs from ichthyol in that it has no disagreeable odor. It is said to be of great benefit in treatment of frostbites when applied as follows:

℞.	Thioli—liquidi		
	Glycerini, āā	℥i	*32*

M. Sig. Apply locally on a piece of gauze.

[Thiol is a hydrocarbon obtained by the destructive distillation of peat. It can be prescribed either in the form of dusting powder or as a brownish liquid containing 25 per cent. of the dry residue. When prescribed dry as a dusting powder it can be mixed with starch.]

CHILBLAINS.

According to Hyde the treatment of chilblains should consist in stimulating applications which tend to restore the activity of the circulation. He advises tincture of iodin reduced one-half in strength, or one part of aqua ammonia and tincture of iodin reduced one-half; tincture of camphor; and ointments of iodin, boric acid, and tar. Camphorated soap liniments and lotions containing sodium bicarbonate are also recommended.

The severer forms of frostbite are treated by surgical measures suitable in cases of gangrene and suppuration of slough.

Fetid Bronchitis.

Progrés Medical recommends the following combination in fetid bronchitis:

℞. Plumbi acetatis
Terpin, āā ....gr. ii | 12
Pulv. opii et ipecacuanhæ ....gr. iss | 09
M. Ft. pil. No. i. Sig. *One such pill three or four times* daily for children from 8 to 12 years of age.

Nerve Tonic.

Eucalyptol is also considered by T. Republica, in *Merck's Archives*, as a valuable nerve tonic, which in his hands has proved very reliable. In all neurasthenic conditions, especially those arising from mental overwork, he finds its action satisfactory, especially if it is combined with synergistic agents, such as strychnin and phosphorus. As the effects of the drug are produced slowly he recommends that the administration in these cases be continued for three months.

Treatment of Breasts.

Brodhead, in the *Post-Graduate*, recommends in the case of women who do not expect to nurse, from any cause, the use of a tight breast-binder. The nipples should be protected with gauze; cotton should be placed in the axillæ, around and between the breasts and the binder applied as tightly as it can be worn with comfort. If it becomes loosened it should be tightened; it should not be removed except for purposes of cleanliness, until breasts are soft and painless. It is best applied when the patient is in the horizontal position. In many cases the binder alone is sufficient to dry up the milk; in other cases it will be necessary to limit the amount of fluids taken. When the breasts become caked and tender it is a good plan to administer large doses of salts, the Rochelle being as pleasant and efficacious as any. —*Med. Standard.*

Antipyretic and Antineuralgic.

Eron, in *Gaz. des Hôp.*, states that citrophen is rapidly absorbed, and for this reason it is worthy of consideration. He states that when given hypodermically it can be detected in the urine in twenty minutes. Citrophen is a compound of citric acid and paraphenetidin. It is a white crystalline powder, acidulous taste, soluble in about forty parts of cold water, and can be administered in doses ranging from 8 to 15 grains—.5 to 1 gm. Homberger, Ehrendorffer and Freudenberg report good results.

Administration of Chloralamid.

Chloralamid is a hypnotic which ranks among the best in treatment of the insomnia of *neurasthenia and mild forms of insanity.* Dr. S. Clevenger, in *Medical News*, gives the following formula for its administration:

℞. Chloralamid ....ʒii 8
Spts. frumenti
Syrupi idæi, āā.......................℥i 32
M. Sig. One-half teaspoonful at a dose. Two or three *times* this sized dose can be given if necessary.

Lettow gives it as an enema as follows:

℞. Chloralamid ....gr. xlv 3
Acidi hydrochlorici ....m. ii } 12
Alcoholis ....m. xv. 1
Aquæ ....℥iii 96
M. Sig. *To be given per rectum.* *N. Y. Med. Jour.*

Removal of Ear-Wax.

Hardened wax in the external ear can often be removed readily by injections of *warm water and soap, soda or ammonia.* Many cases resist this, and require the softening effects of glycerin or sweet-oil for a day or two before syringing. *Do* not bother with these long processes, but use a half-strength solution of hydrogen dioxid in the ear for about five *minutes.* This will disintegrate the hardest plugs, and they can be removed with very little syringing. This process never causes irritation or inflammation. Do not use too much force with the syringe; wipe the ear perfectly dry with absorbent cotton and apply petrolatum; wear a small piece of cotton in the ear for a day or two after removal. —*Phila. Med. Jour.*

Medicolegal.

Jury Not Supposed to Know Value of Medical Services.—To leave to a jury to determine the value of the professional services of a physician as an element of damages in a personal injury case, the number of his calls and consultations at his office alone being put in evidence, the fourth appellate division of the Supreme Court of New York holds, in the case of Carter vs. the village of Nunda, is error. At the most, it holds, the recovery for medical attendance should, under such circumstances, be limited to nominal damages. There is, it says, no fixed and definite schedule of charges of which a jury may take judicial notice by which the value of professional services may be determined, and their value is not a matter of such common knowledge that jurors may be permitted to appraise the same unaided by other evidence, even though such evidence would be advisory, and not necessarily controlling upon their judgment.

Admissibility of Mortality Tables.—The Supreme Court of Michigan says, in the case of Sax vs. the Detroit, Grand Haven and Milwaukee Railway Company, that it has been held in some cases that mortality tables are not admissible in negligence cases in which the injury does not result in death or permanent disability. And it says that in Texas it is held that the disability must be not only permanent, but, total, to admit of such proof, it having been stated there that, when the disability is only partial, such evidence would tend to confuse the jury. But the Supreme Court of Michigan holds here that the tables of mortality are admissible wherever the expectancy of life comes in controversy, though they are not conclusive. For example, upon the theory that the plaintiff had contracted for employment for life, and that the defendant had wrongfully refused him further employment after the expiration of four months, the court says that the jury might take into consideration the probable period of his ability to perform *services; and* the probable duration of his life would, in such case, be an element in that problem. However, in this case there were other elements to be considered than the duration of his life. The contract was, in effect, merely a contract to employ him so long as his service should prove satisfactory. On that account, the mortality tables, the court holds, should have been excluded, even if he was wrongfully discharged for another reason than *failure to give* satisfaction. The discussion in this case, the court makes do also for the case of Leach vs. the Detroit Electric Railway, where it holds, and refers to as being the doctrine of this—the Sax—case, that mortality tables are not admissible in a personal injury case where it is not shown that the injuries of a permanent character.

Mandamusing Board of Examiners.—Dean vs. Campbell *and* others was an action for mandamus that was brought to compel the board of *pharmaceutical* examiners of the twenty-sixth *judicial* district of the state of Texas to issue to the plaintiff a certificate to follow the business and *occupation of* a pharmacist. The district court sustained demurrers *to the* petition. But its judgment is reversed by the Court of Civil Appeals of Texas. The latter is of the opinion that if the *averments* of the petition were true, the plaintiff was entitled to the writ of mandamus. It says that the court is lacking in power to control the discretion of the board of examiners, but *the averments* of the petition in this case reached beyond the point of discretion. They were to the effect that the *plaintiff* passed the requisite examination according to the standard prescribed by *the* board, and that he was adjudged by *the board* as entitled to his certificate, but that the board *wilfully* and maliciously refused to issue it to him. If as a *fact in his* examination he stood the test required by the board, and it was the latter determined that he was entitled to his *certificate,* the issuance of the certificate, the court holds, then became *a ministerial* act, and the wilful failure and re*fusal to issue* it would be a wrong perpetrated upon the plaintiff, for which his remedy would lie as prayed for. To this the court adds *that it* has examined the statutes and the decisions *on the* question of jurisdiction of the trial court in actions of this character, and the conclusion reached is that, if the proper case is made by the petition, the district court has jurisdiction to issue its mandamus to require the board of examiners to perform a ministerial duty.

Medicine and Testamentary Capacity.—One of the alleged grounds upon which was based the contest of a will which the Supreme Court of Missouri, Division No. 1, was called to pass on in the case of Martin vs. Bowdern, was that the testator's mental condition had been weakened and changed by the medicines he had taken to alleviate his sufferings so that he was entirely incapacitated to make a will. He had been sick with consumption or some like affliction and had been confined to his bed from the 8th until the 23d of the month, when he died. On the evening of the 20th, he made his will. On the 8th, it appeared, he was given aromatic spirits of ammonia, to be taken in doses of 15 drops, in water, every hour, suppositories of quinin sulphate, to be used every four hours. On the 10th a prescription of carbonate of ammonia, syrup of ipecac, distilled water, and syrup of tolu was given him, to be taken in doses of a dessertspoonful every two hours. On the 14th, he was given a prescription of carbonate of creosote, spiritus frumenti, and syrup of tolu, to be taken in doses of a teaspoonful every three hours. These medicines were prescribed by his attending physician, and, prima facie, the court declares, must be held to be insufficient to impair his capacity to make a will. And as there was no testimony in the case controverting this prima facie showing, it must, therefore, it holds, be taken as conclusive that the medicines did not impair his mind. Great stress, the court adds, was laid upon the fact that the prescription of the 14th contained whisky—an ounce and a half—and that this was given to him in teaspoonful doses every three hours. But no evidence was adduced that even whisky administered in such doses at such intervals would impair, in six days, a man's mental capacity to make a will, and the court declines to so hold as a matter of law. Wherefore, the court holds that the testimony wholly failed to support this ground of contest.

Injury from Apprehension of Personal Injury.—The basis of the plaintiff's claim for damages in the case of Ward vs. the West Jersey and Seashore Railroad Company was that he was by a gatekeeper carelessly and improperly shut in on a railroad crossing while driving over same and thereby subjected to great danger of being run down and killed by an approaching train, and that by reason of the danger to which he was thus exposed, he was shocked, paralyzed, and otherwise injured. The railroad company demurred. This presented to the Supreme Court of New Jersey the question of whether, in an action for negligence, the mere apprehension of personal injuries, which are not in fact received, will support an action, when physical suffering follows as a consequence of the mental disturbance. Up to the present time, this question seems not to have been settled in New Jersey. Now, however, the Supreme Court thinks that a wise public policy requires it to hold such injuries to be nonactionable. It says that it seems to be universally conceded that mere fright from which no subsequent physical suffering results, affords no ground for action. Where personal injury as well as fright is produced by the wrongful act, the rule is also entirely settled that the jury is entitled, in fixing the damages, to consider the mental agitation as well as the physical injury. But in cases where physical injuries follow from fright, the decisions are not harmonious. Among the courts which hold that there can be no recovery for such injuries, those of Maine, Pennsylvania, New York and Massachusetts, as well as those of England, are mentioned as being prominent. The ground upon which the doctrine of nonliability rests, as stated in opinions rendered by them, is said to be that a person is responsible only for the natural and proximate results of his negligent act; that physical suffering is not the probable or natural consequence of fright, in the case of a person of ordinary physical and mental vigor; that, in the general conduct of business and the ordinary affairs of life, we are bound to anticipate and guard against the probable consequences to those who are liable to be affected thereby, but that in doing so we have a right to assume, in the absence of knowledge to the contrary, that such persons are of average strength, both of body and mind.

Examination by Unfriendly Doctor.—The Supreme Judicial Court of Massachusetts says that, in the personal injury case of Stack vs. the New York, New Haven and Hartford Railroad Company, where the defendant denied the injuries, it was permitted, two days before the trial, to send two doctors, who made a thorough examination of the plaintiff, in company with the doctors employed by him. Nevertheless, after he had closed his case, and after it had called its two doctors as witnesses, the defendant asked the trial judge to order the plaintiff to submit to an examination by another doctor named by it. The plaintiff objected on the ground that his relations with that doctor were unfriendly, but offered to allow an examination by any other physician whom the defendant might select. The defendant declined the offer, and thereupon the judge refused to make the order, ruling that he had not power or right to make it under the circumstances. Commenting on this, the supreme judicial court says that perhaps the words "under the circumstances" so far cut down the seemingly absolute denial of power in the first part of the ruling that it meant only to state emphatically the plain injustice and outrage which it would have been to make the order proposed. The judge probably was justified in assuming the truth of the plaintiff's statement that his relations with the doctor were hostile. He certainly was justified in assuming that the plaintiff had personal objections to him. When the plaintiff coupled with his objection an offer to accept any other doctor whom the defendant might choose to send, bearing in mind the large possibilities that were open by telegraph and rail, he had a plain right to have his personality respected to the small extent that he asked. So, if that was all that ruling meant, as it certainly was all that was needed to dispose of the matter, the court says that in its opinion it was right. Nor does it stop there. But it declares that if the ruling required the decision of a broader question, it agrees with the Supreme Court of the United States, the New York Court of Appeals, and some other able courts, that the power does not exist. The need of the power, it thinks may easily be exaggerated, because, if, contrary to usual experience, a plaintiff should dare to refuse a reasonable examination, it would be the subject of just comment to the jury. And, if the power should be deemed needful to a more perfect administration of justice, the remedy, the court suggests, should be furnished by the legislature. A statute empowering the court to order a view of any place in question, or of "any property, matter, or thing relating to the controversy between the parties," it holds, does not extend to the ordering of an interference with the person of a party by some one out of court, in order to enable him to qualify himself to be called as a witness by the opposing party if the latter sees fit. Moreover, the court says that it can not doubt that, as a matter of history, the power it was asked to assert was a kind rarely claimed or exercised by common-law courts. And, in conclusion, it puts decision, not upon the impolicy of admitting such a power, but on the ground that it would be too great a step of judicial legislation to be justified by the necessities of the case.

AMERICAN.

1. **Sanatorium Treatment in Tuberculosis.**—The importance of early diagnosis of the disease is first mentioned by Bryce, who gives statistics showing the presence of sputum in the different stages of tuberculosis. In the sanatorium treatment two ideas are to be kept in view: the cure of the disease, and failing this, the prolongation of life, and he also divides sanatoria into the private, for well-to-do patients, and the municipal, for the poor. The points on which he specially dwells are discipline, the prohibition of discussion between patients of their cases; provision of mental employment of a suitable character; the taking of detailed family histories; the preliminary treatment of pyrexia; exercise; baths; diet, on which he remarks at some length, maintaining that the increased use of more palatable fats is advisable; the cautious use of alcohol, if at all, the use of proteids such as milk, meat, eggs, etc., up to their limit of assimilation, and massage to stimulate metabolism. Other points mentioned are the effects of reduced air-pressure, dress, symptomatic treatment, personal hygiene, and, of course, care of the sputum, etc. The most important part that the sanatoria will play in lessening the fatalities of tuberculosis is, he thinks, in their being educational centers from which persons will return to their homes and there preach the gospel of cleanliness.

2. **Axillary Hyperidrosis.**—This condition, which is sometimes obstinate and annoying, has been treated by Kolipinski by cauterization of the parts so as to limit secretion by destroying the excretory ducts. In producing these scar tissues he says a local or general anesthetic is unnecessary unless the patient is irrationally timid. The axillary base is washed and shaved. The thermocautery at a bright red heat is applied, with its flat side, from ten to twenty times to the space from which the sweat is seen to ooze, namely, the area covered by hair in the adult; the triangular groove below, when the arm is elevated, for about two inches; the posterior border of the armpit, especially at its middle, and the upper external border near the hairy center. One-half or more of the superfices is turned into burns of the second and third degrees. The cauterizing is done in a very few minutes. A dry bismuth or zinc-oxid dressing is applied, and the patient may resume his ordinary occupation in a few days.

3. **Eustachian Bougie.**—The utility of the eustachian bougie in special conditions is maintained by Lockard, and its dangers are, he thinks, very remote. Infection can be produced as easily as by catheterization. Attention to cleanliness is essential and wounding of the membrane can be avoided by due gentleness; emphysema is likely to be trifling and not important if it occurs. Perforation of the drum can occur only if great force has been used. The most serious objection is the possibility of increase in the trouble, but if, at the first sign of such an aggravation, the treatment is discontinued, no permanent harm can be done. He sums up his conclusions as follows: The bougie, except when used as an electrode, is applicable in two conditions only: stenosis and tinnitus. The therapeutic effects are uncertain; sometimes harmful, frequently beneficial. It effects its purpose in two ways; by pressure upon contracted tissue and by reflex influences upon the auditory center. It should be given a thorough trial in all cases that have resisted other procedures. Its use must be stopped upon the first sign of increase in the local trouble. If care is taken, the dangers said to attend its application will be accidents of the greatest rarity. It has a definite field in aural surgery.

4. **Systemic Disturbances of Ear Disease.**—Minor reports cases in which symptoms of meningitis, intestinal derangements, septic fever, and recurrent attacks of biliary fever were connected with aural disease and relieved by treatment of the latter. He calls attention particularly to the importance of this factor in some obscure general systemic symptoms which usually occur in cases where pus is retained in the middle-ear cavity.

5. **After-Treatment in the Removal of Septal Spurs.**—The importance of subsequent care after removal of septal projections is insisted on by Snydacker, who maintains that no one should attempt to remove a spur from the septum without explaining this necessity, and in cases where after-treatment can not be carried out the operation should not be performed.

6. **Nitrogenous Metabolism in Nephritis.**—Klotz here reports experiments on cases of nephritis to determine the effects of nitrogenous metabolism in such cases. The experiments were made in two periods of five days each, in which the results were rather inconclusive, as he admits. The loss of nitrogen was high in both, the figures for uric acid were well above the normal, and nitrogen and phosphorus showed nothing characteristic.

7. **Medicine in 1800.**—Welch reviews the condition in medicine in the beginning of the century showing the contrast with the present time. He notices particularly the death of Washington and the alleged recommendation by Dr. Dick, of tracheotomy, which was not adopted, and says that the almshouse patients of to-day have more rational treatment than the President of the United States had in 1800. He also reviews the *Medical Repository*, the medical journal of the country in 1800, and especially the paper on improvement and progress of medicine during the eighteenth century, which was contained in its fourth volume. In concluding his paper, he refers to A. R. Wallace's remark as to the progress of the nineteenth century as compared not with the preceding one but with all previous time, which is the only just comparison according to that authority. Wallace enumerates twenty-five discoveries of first rank in the nineteenth century against only fifteen previously in the world's history. Of these twenty-five, four at least were medical, and of the previous fifteen, only one—Harvey's circulation of the blood-can be included in this category.

9. **Varicose Veins.**—The subject of varicose veins, anatomy and histology of the saphenous veins, etiology of varix, which the author attributes to congenital weakness, sex and age, to exciting causes, such as organic disease of the heart, pressure, occupation, etc., the pathologic anatomy and the operative treatment are reviewed in succession by Borden. Arguing from the pathologic condition of varicose veins he advises complete excision in all cases where no contraindications are present, and following this multiple ligation, or excision combined with multiple ligation. In cases where these measures are contraindicated and the entire saphenous is dilated, he recommends the trial of the high ligation of Remi and Trendelenburg. Also arguing from the etiology, pathology, and proneness of varix to extend, he recommends early operation. There is too much tendency toward palliative treatment in this disease, under which it often extends until serious complications occur or serious operations are demanded. By early operation, while the area is small, a complete cure may be obtained, and we would then see fewer extreme cases in later life.

10. **Aphasia.**—Hammond reports two cases in which lesions in the superior and middle temporal convolutions were combined with word-blindness and inability to name objects to a certain extent. From these he concludes that the presence of word-blindness or word-deafness, whether alone or in combination, does not always imply that the lesion is to be found in the higher visual or higher auditory centers or in both, but that a lesion in any part of the speech area may so alter the mechanism of the associated speech centers that any or all the symptoms of sensory aphasia may be induced. The naming sense, he says, is yet to be found. At present it lies in the dreamlands of theory.

11. **Nitrite Treatment in Syphilis.**—Browning notices first the method by subcutaneous injection of nitrites for syphilis, and then refers to his own method based on the theory that vasodilation is required and the need of more permanent, though possibly slower action than is obtained by subcutaneous administration. He says that the nitrites are indicated in all syphilitic diseases of the arteries, as a rule in all specific affections attended by pain, in all syphilitic brain troubles, and especially in the later and hereditary forms of syphilitic disorder—cerebral, spinal, peripheral. This lumps clinical indications rather than differentiates them, but for present and practical purposes it may suffice. With these indications goes the mandate to immediately employ such other and more directly specific agents as the case demands. The title of this paper is intentionally made "Use in Syphilis," not for syphilis. It is understood that the glycerin and erythrol preparations are nitrates. But what is known physiologically as the nitrite action is developed and hence that term is used in this article. In administration he finds that the nitrites produce gastric disturbances which prevent their employment for a prolonged period and the desideratum at present is for more vasodilators at least as slow and prolonged in action as the erythrol salt and at the same time as free from gastric disorders as nitroglycerin. Administration by the mouth answered best. All these drugs are highly explosive if improperly managed, and this fact should be kept in mind when mixing, a practice not to be recommended when dealing with the nitrites. The sodium salt should be given in solution, while the sugar preparation is available in the tablet form.

12. **Tuberculosis.**—The motive of Denison's article is to point out the fallacies of the consensus of opinion of physicians as to the treatment of tuberculosis and the incorrectness of present tendencies toward home treatment. The climate treatment has its advantages, which can not well be supplied by a substitute. Another disadvantage of the consensus of opinion is the tendency to magnify the germ element and neglect the predisposing conditions. What we need is reform in the causes of human degeneration without which the germ can not act.

13. **Drinking Water.**—Huddleston reports experiments with the Schumburg method of purifying drinking water by bromin subsequently neutralized by ammonia, and finds that it is effective. He thinks that it is rapid, practicable and inexpensive, as a pound of bromin retails at from 65c to 75c, and as the amount contained in an orderly pouch, weighing only 4 pounds, can be used to purify the drinking water for a day for a regiment of 1200 men.

14. **Spinal Anesthesia.**—The theory of spinal anesthesia is first explained by Stoner, who accepts the non-continuity of the neurons and their mobility, and holds that the injection of cocain into the cerebrospinal fluid paralyzes the peripheral neuron by gaining access directly to the cell bodies. The motor neurons escape, not because their cells escape, but owing to the direction of the motor conduction and the relation of the end-plates to the muscle fibers. They can not retract their function through the muscle as can the peripheral sensory neuron, through its center organ; of course, the cortical neurons are not affected. This also, he thinks, explains the suppression of the reflexes.

17. **Thyroid Neoplasms.**—Cumston reports his experiments with thyroid neoplasms and their operative treatment, reporting briefly a number of cases. He thinks that enucleation is advisable only in those rare cases of congenital formation, and simple colloid foci, and in cases of recurrence after total extirpation of one lobe. In a large majority of cases, total extirpation is the better plan, its one drawback being the possibility of wounding the recurrent laryngeal nerve. This may occur, though apparently all precautions are taken against it. In his future operations he will follow Kocher's advice to leave a bit of thyroid tissue at this point in order to avoid the nerve. He mentions in conclusion Jaboulay's treatment of desiccation of goiter after exposing it to air through an incision, reports of which would lead him to try it in those cases where extirpation or enucleation is contraindicated.

22. **Resinol Dermatitis.**—Resinol is a proprietary or rather secret remedy used for all sorts of cutaneous diseases and extensively sold. Its effects, however, are sometimes unfortunate, as shown by Heidingsfeld's paper. He reports three cases of dermatitis traced by him to the use of this application and concludes that resinol "possesses dangerous antiseptic and anodyne properties which under favorable circumstances, be it a special idiosyncrasy of the patient or impaired vitality of the tissues, are capable of inducing severe dermatitis, if not actual necrosis of the cutis and obtunding the sensibilities to such a degree that a habit is formed so strong in nature as to cause its constant and exclusive use."

28. **Yellow-Fever Bacilli.**—Reed and Carroll report the investigations which they have been making for the past year or more in regard to the identity and character of the bacillus of Sternberg and the bacillus icteroides of Sanarelli. Their experiments and observations are given in detail and the conclusions at which they arrive are stated as follows: 1. Bacillus X (Sternberg) belongs to the colon group. 2. Bacillus icteroides (Sanarelli) is a member of the hog-cholera group. 3. The various channels of infection, the duration of the disease and the gross and microscopic lesions in mice, guinea-pigs and rabbits are the same for bacillus icteroides and the hog-cholera bacillus. 4. The clinical symptoms and the lesions observed

in dogs inoculated intravenously with bacillus icteroides, are reproduced in these animals by infection with the hog-cholera bacillus. 5. Bacillus icteroides, when fed to the domestic pig causes fatal infection, accompanied by diphtheritic, necrotic and ulcerative lesions in the digestive tract, such as are seen in hogs when infected with the hog-cholera bacillus. 6. This disease may be acquired by exposing swine in pens already infected with bacillus icteroides or by feeding them with viscera of infected pigs. 7. Guinea-pigs may be immunized with sterilized cultures of bacillus icteroides from a fatal dose of the hog-cholera bacillus and vice versa. 8. Rabbits may be rendered immune by gradually increasing doses of a living culture of bacillus icteroides of weak virulence from a fatal dose of a virulent culture of the hog-cholera bacillus. 9. The sera of animals immunized with bacillus icteroides and with the hog-cholera bacillus, respectively, show a marked reciprocal agglutinative reaction. The article is illustrated with photomicrographs and cuts showing the pathologic changes from injection of the bacillus icteroides, and in yellow fever. [See THE JOURNAL, xxxvi, p. 40]

29. **Bacterial Self-Purification of Streams.**—Jordan gives the results of a study of the chemical and bacterial conditions of the Illinois River and its tributaries, undertaken in behalf of the Sanitary District of Chicago. The results of samples taken under varying conditions at various points along the course of the Chicago Drainage Canal to the Desplaines and Illinois Rivers are also given with some observations made on some of the more important tributaries before their junction, and in the Mississippi River below the confluence with the Illinois. The tables show a very marked reduction of bacteria in specimens taken within comparatively short distances. For example in the flow of twenty-four miles between Morris and Ottawa, the river freed itself from a great mass of sewage bacteria with which it was originally laden and at Ottawa this was not greatly in excess of that found in the flow of tributary streams. The character of the Illinois river is such that mechanical agitation and aeration of the water could play but a small part in causing this effect and dilution apparently was unappreciable in this way. Nothing very definite, he thinks, can be stated as regards the action of sunlight, and such evidence as he has gathered does not warrant attaching any great importance to this factor. The influence of the plankton, or the marine life of the surface of the stream, is also still questionable, perhaps more so than that of sunlight, and reasons for this are given. In fact there was a conspicuous lack of abundant plankton life in the stretch of river between Morris and Ottawa where such notable purification occurred. More importance is attached to sedimentation, the conditions for which were nearly ideal, the fall of the river in its lower 225 miles being only 30 feet and the sedimentation still further accentuated by the presence of several dams. This settling out of suspended matter and the entanglement of bacteria in the same must have been an important agency in the reduction of the latter. Jordan remarks also that all the instances recorded in the literature where marked bacterial purification have been observed are precisely those where the conditions for sedimentation have been most favorable. The limitation of food-supply for bacterial life, however, is an element which he thinks has received insufficient consideration in the past, and in this he thinks is the most reason for the bacterial self-purification of streams. The excessive removal of bacterial food from the water probably is due largely to the bacteria themselves, and they explain this fact. There is no accumulation of foul mud in the bottom of the river, notwithstanding the fact that sewage has been poured into it for 35 years. The solid matter, therefore, is destroyed either in suspension or after sedimentation. The river as a whole can be considered a great septic tank for bacterial purification. [See editorial pages.]

39. **Suprarenal Gland.**—According to Bates the extract of the suprarenal gland is the best hemostatic known, and while powerful is not objectionable in any way. It is the most powerful known astringent; the only one which can be instilled in all diseases of the eye without injury. It is the most valuable remedy for ear inflammation and improves the hearing when applied to the Eustachian tubes after other treatment has failed. For the nose and throat there is hardly any substance that we are acquainted with which has so many beneficial, and so few deleterious effects. Its use in hay-fever, edema, Graves' disease, edema of the glottis, acute and chronic bronchitis, asthma, pulmonary congestion and edema, hemoptysis, etc., are mentioned at length and he claims that it is the most powerful known heart stimulant. In three minutes after 5 grains of the dried gland have been swallowed, the weak pulse of organic heart disease becomes stronger and the high-tension pulse of the laboring heart becomes regular. The normal heart is not embarrassed by an ounce of the powder. He says in conclusion: "Let me repeat that the suprarenal extract is the most powerful astringent, hemostatic and heart stimulant known. The field of its usefulness is rapidly widening. It is a safe remedy, and the reason why no bad effects have followed its administration is because we are using as a drug one of the secretions of the body which is necessary to life.

40. **Paroxysmal Delirium.**—Under this head Hollopeter reports several cases of delirium apparently due to autointoxication from the intestinal tract in children, and offers the following as a brief summary of his views. 1. The fever incident to intestinal autointoxication has no classified train of symptoms, varying in intensity and regularity according to the nervous mechanism and heredity of the child. 2. The symptoms manifested by autointoxication affect the nervous system so variously, that it is a question whether a classification based on the localization of the seat of intestinal irritation can ever be brought about. 3. The symptoms manifested by intestinal ptomains express themselves in symptoms suggestive of typhoid fever, meningitis, and malarial fever, so frequently, that without differential diagnosis, many cases are thus treated.

42. **Depilation.**—The use of the electric current to remove superfluous or misplaced hairs is described by Schamberg, who makes one or two suggestions. He advises against the use of the steel needle, as reversal of current may produce a deposition causing a tattoo mark. He uses the iodo-platinum needle, as a reverse would not make any difference. He also considers that it is not advisable to attempt to remove a fine growth of dark hair from the upper lip of young brunettes, but instead to prescribe some bleaching agent such as hydrogen dioxid which causes the hair to lose its color and become less conspicuous. There is also some reason to believe that the continued use of this agent may ultimately weaken the hairy development.

49. **Oxycamphor.**—This preparation, which is oxidized camphor, in which one of the hydrogen atoms has been replaced by the hydroxyl molecule OH, was first prepared by Manasse, of Munich, who found that its physiologic action was quite different from pure camphor, as it was an excitant, did not alter the blood-pressure, but decidedly influenced the respiration. Hirschfelder found it beneficial in the treatment of asthma, though in some unsuitable cases it has failed to have the slightest effect in spite of vigorous dosage. In one case it seemed to bring on the attack. The preparation which is sent out by the manufacturer as oxyphor contains 50 per cent. of oxycamphor, and this may be given in doses from ½ to 2 drams. He has been in the habit of prescribing it dissolved in simple elixir in the strength of 1 to 7. He has reports from Dr. Graves that it has been decidedly beneficial in whooping cough of children in doses of 5 to 30 minims of oxyphor. He says, "To sum up our experience with the drug, it is safe to say that we have in it a valuable addition to our pharmacopeia, one that we can safely use to take the place of various narcotics in the treatment of different forms of dyspnea."

58. **Diabetes.**—According to Vaughan, diabetes mellitus is a name used to designate the fact that the body has lost more or less its function of normally metabolizing carbohydrates. *According to this definition, diabetes and glycosuria are by no means synonymous.* The capability of the individual for the utilization of carbohydrates is limited. A healthy working adult thrives best upon from 18 to 20 ounces of carbohydrates daily, while he may dispose of two to three times this amount, for a time at least. It is not probable that the healthy man

can take enough starch to cause sugar to appear in his urine, but with less complex carbohydrates, the facts are otherwise and a temporary glycosuria can be induced by an excess of sugar. This, however, does not occur very often. The tests for sugar are reviewed and the necessity of the greatest care in making these emphasized. The class of foods, proteids, fats and carbohydrates and the proportion of each required by a normal man are enumerated and Vaughan lays down the diet tables for a case of diabetes, which differ from those usually given in that they contain relatively more fat and less proteid. He thinks that proteid feeding is overdone in this disease and it frequently happens that the sugar decreases by cutting down the proteids. The diet is arranged for a regular progressive course of seven days, and when the fully non-carbohydrate bill of fare of the last day is reached it should be continued for at least five days. the urine being tested during the last two. If the sugar disappears under the non-carbohydrate diet the case belongs under the head of mild glycosuria, but if it persists, the severe form may be said to be present. If it is the former, we must determine to what extent the patient has lost the power of utilizing the carbohydrates in his food and try the tables given in inverse order for five days and test the urine regularly until the sugar reappears. Having thus ascertained the amount of carbohydrates he can utilize, a steady diet is fixed. In those cases which continue to excrete sugar under non-carbohydrate diet. after the last days of the series, the dieting becomes a very serious matter and Vaughan thinks it best to insist that a non-carbohydrate diet should be followed one week out of every four. The short and frequent periods are more easily borne by the patient and are more beneficial to him. During the interval from 100 to 120 gm. of white bread or its equivalent should be allowed daily. These cases are incurable with present means, and the best we can do is to prolong life.

59.—See abstract in THE JOURNAL, xxxv, p. 1046.

65. **Problems in Pediatrics.**—In this address the subjects taken up by Holt are the present status of diphtheria antitoxin, in which he shows the advance and great success in the treatment since the introduction of this agent; next Koplik's sign in measles, which he finds to be characteristic of this disorder and valuable in diagnosis, though not sufficient to enable us to recognize the disease before the possibility of infection to others. Milk sterilization and infant feeding, with the milk-supply of various cities are also discussed at considerable length. He believes that we need to educate parents in the conditions that are essential to life and the normal development of their children and to reduce susceptibility by increasing resistance.

71. **Antero-Posterior Subdivision of the Bladder.**—Fuller reports a case of transverse division or contraction of the bladder anteriorly to the urethral openings, dividing it into two parts. Two cases were observed by him, in both of which uncomfortable symptoms of increasing difficulty of urination began in early life and finally ended in retention. In both cases, it is true, urethral stricture existed, the cause for it in the first case being obscure, and possibly due, as he says, to long-continued vesical tenesmus. In both instances, however, it appeared to be insufficient to account for the retention. The first case was relieved by cutting through the vesical portion of the lower margin of the aperture opening between the two chambers down to the vesical floor, the assistant holding his finger in the rectum and maintaining steady upward pressure under the partition, while a pair of heavy serrated scissors were introduced through a suprapubic opening. dividing the partition wall down to within a quarter of an inch of the assistant's finger. After dissecting apart the cut edges of the partition as much as possible with the finger introduced from above, a large peritoneal drainage-tube was inserted and maintained between the cut edges. Temporary suprapubic drainage was also established. The recovery was uneventful and cure complete.

76.—See abstract in THE JOURNAL, xxxiv, p. 688.

80. **Visual Defects as Effecting the Earning Capacity.**—The conclusions at which Hansell arrives from his discussion of the amount of injury to the earning capacity of the individual by visual defects are stated as follows: Blindness is that degree of loss of vision that incapacitates one from earning his living in any occupation requiring the use of the sense of sight, the degree varying according to the demands of the occupation. Vision of less than one-half diminishes the earning power and the less the vision the greater the loss of the earning power. Monocular blindness is not incompatible with full earning capacity. The loss of earning power owing to defective vision may be computed according to a simple system based upon the ratio of the loss of vision to the full earning capacity at any age and in most occupations.

82.—See also title 108.

84. **Phototherapy.**—Stelwagon describes his personal observations of Finsen's method of treatment. The results are good; of this, he says, there can be no question. There are some disadvantages in the treatment of cutaneous tuberculosis, which is the form of disease there treated, the chief one being the duration of the treatment and the cost of apparatus, expense of treatment and close attention required. The principal criticism, however, made by those who have visited the institute and studied the method is that, in the mild and moderate cases at least, as rapid results can be obtained by other plans which have long been in vogue and are less expensive. His experience in the treatment of lupus in Philadelphia justifies this criticism. He thinks, however, there may be a difference in the type of disease to some extent. American skins do not seem to be so easy a prey to tubercle infection and the disease is here milder and more amenable to treatment than most of the European cases seem to be. It is probable, moreover, that, with further improvements, the light treatment may be made simpler and less protracted and expensive.

85. **Cataract Operations and Insanity.**—Posey reports two cases in which removal of a cataract in chronic insanity produced a rapid and complete cure of the mental disease. In both cases there seemed to be, from the history, a direct relation between the mental disease and the visual failure, and this may account for the success.

86. **Diet in Typhoid.**—In the majority of typhoid cases milk is the safest and most satisfactory diet, and Tyson does not favor the use of the soft foods which have been advocated by certain authorities. He does not, of course, hold exclusive opinions on this subject. He admits that under certain conditions animal broths and albumin water, consisting of the white of an egg mixed with water, may be used as a substitute. The objection to animal broths that they are specially favorable culture-media is, he thinks, overestimated. If given fresh they should be sterilized by heat, and it is doubtful whether any food does not become a culture-medium in the stomach. In case of hemorrhage, an immediate reduction in the amount of food should be made. It is better for some time to give no food at all, though in an uncomplicated case he gives from 4 to 8 ounces of milk every two hours. In case of peritonitis the indication for the arrest of peristalsis exceeds all others and this can be secured in no better way than by total omission of the food. Where total cessation does not seem necessary, the quantity can be very much reduced—one-half ounce or one ounce every two hours until the danger is passed. In convalescence he lays down an arbitrary rule which he thinks is on the safe side, namely, adherence to liquid food until the temperature has been normal for a week. After that he allows soft boiled eggs, and in two or three days soft milk toast and other soft foods are added from time to time until a reasonable mixed diet is taken. Chicken is one of the foods last allowed.

88. **Heller's Albumin Test.**—Fussell describes the various rings observed in Heller's nitric-acid test for albumin and concludes his article as follows: It would seem after these observations and the demonstrations that in making Heller's test three rings are formed: 1. The color ring. This ring forms in practically all urines, whether there is albumin present or not. It is specially marked in concentrated urines rich in

coloring matter, and in the urine of patients taking iodid of potassium or salol, or indeed any of the coal-tar products. It is at the point of contact between the acid and urine. 2. The white zone of albumin which forms at the line of contact between the urine and the acid, but always above the dark, constant, color ring. This ring is of a densely opaque white, and I think this is especially the fact when there is but little coloring matter in the urine. If there is a small amount of albumin present, however, as in urine containing pus, the ring is less dense, but nevertheless in close contact with the layer of acid and immediately above the color ring. 3. The urate ring, which forms high above the albumin ring, if albumin is present. The color ring forms at the line of contact of the acid and urine, and the color usually disseminates into the acid below and sometimes into the white albumin ring above. It is always below the albumin ring. The white albumin ring also forms at the point of contact of the acid and the urine; it is wholly in the urine and always above the color ring, though later on it may be somewhat discolored by it. The urate ring, a white thin zone, quickly forms, is far above, sometimes one-quarter or one-half inch above, the albumin ring, and is easily dissipated by heat.

92. **Hip-Dislocation in Typhoid.**—Spontaneous dislocation of the hip in typhoid fever, though comparatively rare, has some literature and has been noticed at length by Keen in his "Surgical Complications and Sequels of Typhoid Fever." Weigel reports a case in a girl 8 years of age, which caused considerable difficulty in its treatment, and still remains dislocated. He thinks the recurrence of luxation can not be attributed entirely, if at all, to relaxation and distension of the tissues and lack of suction power of the joint. He is inclined to think rather that the gradual lengthening of the ligament and distension of the joint-capsule permitted the head of the femur to slip out of the acetabulum without producing a rupture of the structures, which were simply carried upward, and when the joint was restored, the capsular ligament became folded on itself and prevented a perfect replacement. He has had a partial improvement in the case reported, the limb is better and stronger and more useful in every way than if nothing had been done.

93. **Uterine Cancer.**—After remarks on the diagnosis of malignant uterine disease, Crossen gives the report of a number of questions which he submitted to Dr. Carl Fisch, the pathologist, and their answers. 1. As to whether a positive diagnosis of carcinoma or sarcoma can be made from uterine scrapings, which is answered in the affirmative, though difficulties may arise in malignant adenoma. 2. Can malarial disease be excluded by such examination? Also answered in the affirmative. 3. Does malignant disease from the body of the uterus always involve the endometrium in the early stage so that a diagnosis can be made of the scrapings before the tumor has passed beyond the reach of radical operation? The reply to this question was that unless there is a degeneration of the myometrium without involvement of the mucosa or settling of a metastasis from another tumor, and in cases of carcinomatous degeneration of fibromatous uterus, the scraping should reveal the condition. As regards the early diagnosis of these exceptional conditions, the examinations of scrapings would, of course, yield only negative results. 4. Do fibromata really undergo malignant degeneration, and if so, is it carcinomatous or sarcomatous, and at what age does it occur and how may we know of the occurrence of the change? The reply to this was that fibromyomata frequently undergo malignant degeneration, the result being nearly always sarcomatous, though myxomata and even chondromata forming metastases are often observed. These changes are most frequent at the menopause, though they may occur earlier, with great thickening and enlargement of the uterus in some cases and marked thinning and dilatation in others, sometimes with the formation of pyometra or concomitant signs. The early stages can not be reached by direct examination except where a tumor is removed for other reasons. This sarcomatous change may remain latent for a long time, to light up with great intensity after some injury.

103. **Hands and Feet Affections.**—A patient suffering from the commoner affections of the hands and feet is hardly likely to think of a medical practitioner as a resource for relief. The average layman, or laywoman, gets the idea that the physician's work does not go beyond a bad complexion and similar affections. Barbers, druggists and especially chiropodists and manicurists have become specialists in this line, to the damage of their clients, and in this article Dyer directs attention to what we call the commoner affections of the hands and feet, viz., corns, bunions, warts and diseases due to the sweat-glands. In the summer many people complain of the hands and feet perspiring, and this may often result in a chronic condition of hyperidrosis and is often complicated with a tendency to inflammation, causing much pain and possibly confining the patient to bed. The condition is apparently easy to treat. 1. Advise the use of white castile soap and restrict excessive drink. Give a small dose of strychnia internally for a long period, about six weeks. For the hands, the use of a 3 to 5 per cent. alcoholic solution of salicylic acid frequently during the day; for the feet, a like remedy in powdered form, viz., salicylic acid, ½ dram; tannin, 1 dram; powdered arrowroot and rice starch, of each half an ounce, dusted in the stockings every day. Where the feet are inflamed and not blistered, simple bathing for 20 to 30 minutes in hot water with 4 ounces of laundry starch to the gallon should be of service before the use of powder. In the more chronic condition lead water may be used on cloths applied at bedtime, and if the blisters suppurate, nothing relieves better than a 5 to 10 per cent. solution of ichthyol. The commoner conditions of the nails of the hands and feet are: ingrown nails, run-arounds, hangnails, horn-nail and felon. The hangnail often causes paronychia, and as often the felon. It should be held in place and collodion painted over it. When infection occurs, touch the spot with carbolic acid and mop afterward with alcohol, or touch it with nitrite of silver. If the infection goes further, nothing is so good as a 1 to 1000 bichlorid dressing kept constantly wet, which often aborts felons and is much better than the soap and sugar and other compounds of household practice. The ingrown nail can be treated by scraping a notch and clip to keep the flesh away from the nail. In severe cases it may require the removal of a portion of the nail and redundant skin. Warts will almost always disappear under daily painting with salicylic acid in collodion (5 per cent.) solution, excepting in the acuminate type. Other remedies which he uses are formalin solution, corrosive sublimate, and sulphur. Corns and bunions are sacrifices to civilization and the original conditions are relieved by the wearing of properly adjusted shoes and protecting the part with a simple cotton and collodion dressing. A useful and convenient remedy is tincture of iodin. Bathing in starch water is also advisable and should be practiced twice a day. He speaks in condemnation of the commoner practice of letting chiropodists work on the feet with a knife that is always unclean, helping only to promote disease and the practice of the operator. For the soft corn between the toes, ordinary greasing and putting a film of cotton over it usually will suffice. Salicylic acid plaster, 10 per cent., is useful for flat corns not especially painful. Most of the local applications are suitable, but the above seem to be the ones here specially recommended.

108.—See also title 82.

118. **Dissection Wounds.**—Bacon discusses the etiology of dissection and operation wounds, considering first the nature of the infecting microbe, and second the effect upon the virulence of the source from which it comes. The foremost place as an infecting agent must be assigned to the streptococcus pyogenes and the next to staphylococcus pyogenes aureus. It is probable that all the well-recognized pyogenic germs may, under favorable circumstances, give rise to more or less virulent septic processes when inoculated, but the author does not have at hand the reference to such cases. The anthrax bacillus is one that might be likely to produce a condition that would probably come under the title of his paper, also the bacillus of malignant edema. The tubercle bacillus is notoriously the cause of infection in the so-called "anatomical tubercle," and

while he has not found records of general tubercular infection from these causes, he thinks they are possibly not uncommon. Other germs mentioned are the diphtheria bacillus, the virus of syphilis, etc. The effect upon the virulence of the infecting germ of the source from which it is derived is discussed at some length and he points out that there is a comparative difference as regards the danger of the wound at a recent, with one received at a delayed, autopsy, which is due to the bodily warmth and the lack of development of defensive proteids in the dead subject. The chilling of the body and the beginning decomposition of the tissues and struggle for existence with saprophytic bacteria probably so affect the environment as to make it a less suitable culture-medium for the virulent pyogenic germs.

122. **Female Deterioration.**—The question whether the alleged deterioration of the human female as a factor in reproduction is a fact, is treated by Myers, who says that the toiling woman, with her interfering muscularity, may show equal deterioration with her overstrained sister of leisure. The intellectual woman need not fear maternity if she is able to let her intellect lie fallow long enough for her system to be stored with the necessary commissary supplies. But he thinks there is a constant tendency to mend matters in the natural processes of nature. The question of clothing, habits, education, etc., are also mentioned in their alleged effect upon deterioration.

British Medical Journal, December 22, 1900.

Quantitative Color-Tests. KARL GROSSMAN.—The defects of the Holmgren test are pointed out by Grossman, who shows how central scotoma may affect the quantity of color-perception according to the area of scotoma. Vision may be perfectly good at short distances, but, for this reason, fails at greater ones and a serious accident might follow. For the purpose of detecting such defects he has devised an instrument consisting of colored glasses used with transmitted light of varying power, thus putting the individual under conditions such as he meets in his occupation as seaman or railway employee. The rotating disc contains plates of clear and colored glass with an arrangement for varying apertures and size from 10 mm. to pin-point and intensity from light to dark, thus offering an unlimited variety of lights, both colored and white. The apparatus may serve as the basis for the adoption of a standard for the quantitative measure of color-perception, as by it the smallest central scotoma can be detected.

Remarks on Chronic Enlargement of the Pancreas in Association With Or Producing Attacks Simulating Biliary Colic. GILBERT BARLING.—Three cases are reported by Barling, which had the common feature of enlargement of the head of the pancreas with attacks of colic and more or less complete blocking of the biliary duct. On account of the thickening of the head of the pancreas, it was impossible to say with certainty that pancreatic calculus did not exist, though none could be detected. In two of the cases there was an ill-founded diagnosis of gall-stones. In the other, two gall-stones existed and possibly, by inflicting damage on the common duct in their passage, directly induced the pancreatic inflammation. It is impossible, at present, he thinks, to make a positive diagnosis between certain affections of the biliary apparatus and chronic inflammation of the pancreas. If operation is required, however, it is fortunate that the same steps have to be taken in either condition. If the situation calls for operative interference with pancreatic enlargement of this kind, two methods of treatment offer themselves: very prolonged drainage of the gall-bladder is the method usually employed after cholecystectomy, or anastomosis between the gall-bladder and duodenum. In the second case reported drainage was employed and seems to have acted beneficially on the pancreas. In the fourth case the gall-bladder was joined to the duodenum, with resulting cure of jaundice and other symptoms complained of, though there was still some enlargement of the pancreas. He thinks that these cases suggest a more hopeful explanation of the occurrence of thickening of the head of the pancreas with jaundice than has hitherto been held possible.

Some Points in the Treatment of Spinal Abscesses. A. H. TUBBY.—The following points of treatment in cases of spinal abscess are emphasized by Tubby: 1. Do not wait to open a spinal abscess until the skin is reddened and involved. 2. As far as possible open the abscess at certain "seats of election," the places of evacuation to be decided by the direction taken by the abscess and by the surgeon. 3. Wherever evacuation is decided on, let it be done as far as possible away from the groin, and in such a position that more than one opening can be made into the abscess cavity. 4. Carefully cleanse the cavity and rub the interior thoroughly with menthol or iodoform solution. 5. Avoid drains of all kinds. 6. Be careful to carry out perfect aseptic measures from first to last. He enlarges upon these respectively. As regards the "seat of election" he mentions a case where by waiting, the abscess enlarged in its femoral portion and outward from the abdomen, under treatment by prolonged rest. This multiple opening was employed, with recovery. The importance of making more than one opening of the abscess and sac away from the groin as a cardinal point, is emphasized in the treatment of these cases. Evacuation is likely to be more complete, pockets of pus not so likely to remain, and all parts of the cavity can be brought within reach of the sharp spoon, the irrigator and the cleansing sponge. Applications to the sac-wall are also rendered more easy, and the greater the number of incisions that can be made without risk, provided they are all sewn up after the operation, the better will be the result.

The Lancet, December 22, 1900.

Pulmonary Tuberculosis in Early Childhood. ARTHUR LATHAM.—Latham holds that the majority of cases of tuberculosis in infancy are more probably due to infection through the digestive tract by milk than to air infection, and he says in support of this view that the whole picture of pulmonary tuberculosis in children differs from that in adults. In children the process is usually acute, the seat of infection and the breaking down of tissue is comparatively seldom reached. We often find tuberculosis in the bronchial glands while the lungs are practically unaffected, which is hardly ever seen in adults. He, therefore, holds that the disease is communicated through the lymph-glands in infants, though in the adult aerial infection is undoubtedly most common. The clinical varieties of pulmonary tuberculosis in children are numerous. Until the child is 3½ years of age it is a common development from infection of the bronchial glands and spreads from these glands to the lungs rather than from the lungs to the glands. After the age of 4 years the lesion found becomes more and more comparable with those in adults. The conditions which he found up to the fourth year he classified as follows: 1. Tuberculosis of the bronchial glands, which may lead to no special symptoms, and the diagnosis of this condition is described, especially the cough, alteration in the voice, venous hum, pressure symptoms, etc. Similar enlargements from other causes are much less frequent than from tuberculosis and these points will enable us to differentiate. 2. Miliary tuberculosis is rare in children excepting in cases of general tuberculosis. The general symptoms always precede the localizing ones; the latter may be absent. The child gradually wastes and this is followed by general malaise, anemia and anorexia. In most of these, however, digestive disorder is not prominent. The progressive wasting with slight fever arouses suspicion and this becomes assured by definite localizing symptoms as the time progresses. The differences between marasmus, typhoid fever, congenital syphilis, etc., are described. 3. Tuberculous bronchopneumonia, which may be either acute or chronic. In the acute cases there may be nothing to justify the diagnosis of tuberculosis, but in many cases, toward the end, we have evidence of meningitis. In the more chronic form, we have the initial stage with general symptoms followed by development of pulmonary signs and symptoms. Hemoptysis is rare, as are also signs of associated pleurisy. The disease is rarely arrested, but generally proves fatal in from one to six months. Diagnosis from simple bronchopneumonia is always difficult. The insidious onset is one of the special symptoms. If the attack begins with acute symptoms in previously healthy c dren bronchopneumonia is nine times out of ten non-tu lous. The appearance of the child may help us, but Latham remarks on a copious crop of downy hair being frequently found on the back of children who become tuberculous. The family history and associated enlargement of the bronchial glands or tuberculous disease elsewhere is of importance, and if we can get the sputum, all difficulties may be solved. Children mostly swallow their sputum, and in children under 6 years of age, if expectoration is profuse, it is probably tuberculous. Sometimes a gentle emetic may aid us in obtaining a small mass of purulent matter which reveals definite evidences. After the fourth year, and still more after the sixth, the type conforms more to that of the adult, but there are some differences. There is not the same tendency to begin at the apices and extend downward nor to form fibrous tissue. Extensive excavation is less common; hemoptysis and laryngeal complications are rare; pneumothorax is rare and not infrequently meningitis ends the scene. The physical signs are of less importance in children than in adults; a cracked-pot sound may be of no importance whatever. The prognosis in any form of tuberculosis is grave. Tuberculosis of the bronchial glands with marked pressure is also serious and the same is true in tuberculous form of general bronchopneumonia. The cases where the processes start during acute stages of measles or whooping cough are unfavorable, but when the tubercle bacilli are grafted on to the ordinary bronchial pneumonia which follows these diseases, the chances are better. The prognosis should be guarded, as many patients who seem hopelessly ill, get well, and sometimes where the disease appears to be quiescent, they succumb to a trifling ailment. In the adult type occurring in children, the prognosis is more favorable and frequently when taken early these patients do remarkably well. The aim in the treatment is to prevent further infection. Other measures to be adopted must follow the general lines of treatment of the disease in the adult. Fresh air, sunlight, precautions against cold and fatigue, equal temperature, a small amount of stimulants sometimes, cod-liver oil and small doses of other ordinary drugs, such as quinin, creosote, etc., are also occasionally of value. The symptoms can be treated as they arise.

Observations on Compressed-Air Illness. Frederick R. Wainwright.—The writer reports his experience with caisson disease in the Waterloo tunnel works of London, where, considering the pressures employed and the length of shifts, there were remarkably few cases of illness. The men were carefully examined before allowing them to work, the average age being just over 30. During a period of over five months, only 47 cases of illness due to the work came under treatment, in 40 men out of the 120, two having three attacks each and three having two. These figures include only cases of sufficient severity to call for treatment. Most of the men were free users of alcohol. The symptoms are described: Pain in the ears, joints, epigastric pain, vomiting, headache, dizziness and paralysis in one case, with no fatalities. The most important points in the diagnosis are the time and manner of the onset. He would not admit a case to be due to compressed air where more than twelve hours had elapsed between the time of leaving work until the onset of symptoms. Rheumatism and osteoarthritis are not likely to be mistaken for joint pain of compressed-air illness. The absence of any rise of temperature in the latter, together with the sudden onset and the freedom from physical signs, serves to define it. He considers ventilation an important preventive agent, the amount of carbonic acid present being a prime factor in the etiology of the disease. Of the pathologic theories, he accepts that which attributes the condition to supersaturation of the blood with gases due to compression, and he thinks that carbonic-acid gas is observed in the greatest amount. He has never been able to discover any remote effects. In one man, 42 years of age, who had worked in compressed air for varying periods during several years, there was marked arteriosclerosis apart from any cardiac or renal disease which could be discovered. Whether this was due to the occupation or not he could not say. In the great majority of cases only one treatment is necessary, and that is recompression with slow locking-out or reduction of pressure. For this purpose a medical air-lock was erected and utilized. The amount of pressure needed for relief depends more on the severity of the case than on the original pressure which produced the symptom. Decompression must be slow. He would not reduce pressure quicker than at the rate of 1 pound in three minutes. In his experience this never failed to stop the pain, though there are exceptional cases where the latter returns. This, he thinks is due to the creation by the first attack of a *locus minoris resistentiæ* which renders the passage of air into the tissues easier than escape by way of the respiratory system. In these cases he uses morphin hypodermically in fairly large doses.

Presse Medicale (Paris), December 12 and 15.

Mechanism of Spinal Cocainization. Tuffier and Hallion.—Extensive research on dogs has demonstrated that the anesthetic action of subarachnoid injections of cocain is due exclusively to the cocain. This specific action affects the spinal roots, and is almost exclusively confined to them. This refers solely to the anesthetic action. Certain by-effects may possibly be due to the diffusion of minute amounts of the cocain to the nerve cells of the cerebrospinal axis.

Cultivation of the Microbe of Soft Chancre. Bezançon.—The writer announces that Ducrey's bacillus grows readily on gelosed blood.

December 15.

Localization of the Lepra Bacillus. E. Jeanselme.—The writer has returned from a special expedition in the Orient, undertaken for the purpose of studying leprosy. He is convinced that bacteriologic examination will prove of great assistance in dubious diagnoses of leprosy, but warns that the bacilli, after having invaded the entire organism, may disappear completely, merely leaving a sclerosis in their track. The chief localizations are the nasal and bucco-pharyngeal mucosa, but all the secretions and even the excretions may be virulent, except the urine, which does not contain bacilli. Prophylactic measures should therefore aim to sterilize the nose, mouth and skin, with occlusion of all ulcerations and compulsory disinfection of garments, linen and all vessels, etc., used. The child of a leprous woman should be taken away from her immediately after birth and never given to another woman to nurse.

Sodium Bicarbonate for Dressing Wounds. J. Casteret.—In all cases in which the vitality of the tissues requires to be stimulated, the bicarbonate has proved the best of all dressings in Casteret's experience with 300 patients during the past two years. In case of moderate suppuration and superficial traumatism it is more effective associated with antiseptics. In severe suppuration or mortified tissues the bicarbonate should yield place to antiseptics, but when the process of repair commences it becomes useful again. The purulent focus is copiously irrigated with an antiseptic solution, after which the bicarbonate dressing is applied. This antiseptic irrigation is repeated each time the dressings are changed. The solution used is 20 to 60 gm. per 1000, and the dressings kept moist. An abscess heals in ten to fifteen days under this treatment and the effect is surprisingly satisfactory in superficial traumatisms, varicose ulcers and burns, lymphangitis and certain dermatoses in which the indication is merely for a stimulation of the vitality of the tissues.

Revue de Gynecologie (Paris), iv, 5.

Treatment of Metritis. Pozzi.—Acute or chronic metritis of the cervix may occur independently of any lesion of the fundus, but it is rare. If it persists it is liable to compromise the nutrition of the entire genital apparatus. Medical treatment may be sufficient in the early stages, and should certainly be tried, but surgical intervention should be sought before the lesion has become propagated by the mucosa and lymphatics. The most prominent symptom is the persistent subinvolution of the uterus and dilatations in the venous system from the chronic congestion of the organ. The ovaries frequently become affected in turn, small cysts developing in the follicles, with hypertrophy and apoplexy of the corpus luteum and pain in the lumbar region. This condition resists all medical treatment and even amputation of the cervix has little effect on the ovaritis at this stage. Pozzi considers laceration of the cervix almost the rule even in normal accouchements. Any lesion of the cervix acts like a thorn in the flesh, irritating the trophic nerves and entailing vasomotor disturbances. Removing the thorn by amputating the cervix puts an end to the congestion and pain. Since lesions of the cervix have such serious and far-reaching consequences, it is imperative to cure them in the early stages. The first indication is asepsis of the vagina with a dressing over the cervix to isolate it from the remainder of the region in case of gonorrheal infection, and collect the secretions. Antiseptic injections are also necessary, and if indicated, application of silver nitrate, iodin or creosotal to the ulcerated surface, or possibly yeast. The thermocautery and curette are inadequate and unreliable. Excision is the only treatment for an inveterate lesion of the cervix, followed by immediate occlusion of the wound by suturing the flaps over it. He prefers biconical amputation with complementary *évidement* or scooping out of the commissures. Sclerogenic lacerations especially indicate operation and the fibrous irradiations should all be followed and removed. By suturing the commissures afterward, the external to the internal mucosa, all tendency to stricture is obviated. This operation not only removes the cause, but acts indirectly on the involution of the fundus and on the ovulation. Backache and dysmenorrhea gradually subside. Another variety of metritis occurs in nulliparæ from narrowness of the orifice of the cervix interfering with the drainage. It requires stomatoplasty by *évidement* of the commissures with consecutive asepsis, antisepsis and exeresis as outlined above. In case of very mild infection and hyaline catarrh it is unnecessary to excise tissues only slightly altered.

Semaine Medicale (Paris), December 12.

Spinal Cocain Analgesia. T. Tuffier.—An experience of thirteen months with this method of analgesia, which Tuffier has applied in 252 operations, has established that there are no symptoms of shock and that the patients return more rapidly to the physiologic condition than after general anesthesia. The analgesia is complete and sufficiently durable, while careful study of the patients during and after the operation shows that there is no injury to the medullary system, either immediate or remote, nor local operative complication. From the moral point of view he has always found the most complete indifference to the operation, especially in men and in private practice. As he has mentioned in his previous reports, one patient died during the day following an operation for eventration. The autopsy disclosed old and severe cardiac lesions, with congestion and edema of the lungs, rendering the fatal termination inevitable. This is the only death that has occurred in his experience. In 20 per cent. of his cases the analgesia proceeded without the slightest subjective or objective symptoms. In 40 per cent. nausea occurred, and he has remarked that this is most liable to happen in cases with slight tension of the cerebrospinal fluid. When the fluid escapes like an ejaculation there is a minimum of incidents, but when it merely trickles. the analgesia will be as complete, but is liable to be accompanied by some annoyances. Nausea is much more frequent after large doses, 25 to 30 mg. A general slight malaise is sometimes observed, commencing about five minutes after the injection and never lasting more than fifteen minutes. Vomiting occurs from five to fifteen minutes after injection in 20 per cent. It is more frequent in men than in women and much more frequent in urgency operations when the subject has not been prepared. Tuffier is hopeful that research will suggest a means to abolish the vomiting in these cases. The subject rarely vomits more than three or four times, but in three cases vomiting recurred a number of times, including one case in which eucain had been used. He now rejects all substitutes for cocain. The brain is not affected and the muscles are completely relaxed, as in chloroform anesthesia, although the power of movement is retained, but the movements are less precise than in the normal condition. The rhythm of the heart is not altered. but the pulsations sometimes become more frequent. In 30 patients the pulse was 80 at the close of the operation and it has been known to reach 120. The respiration continues physiologic. there is no hypersecretion nor congestion in the bronchi. but the inspirations are sometimes deeper. In 5 per cent. of his cases there was incontinence of gases or fecal matter. As the mucosa of the rectum becomes insensible the anus misses the reflex tonicity and is liable to relax under the influence of a violent effort, pressure on the rectum during the ablation of a retrouterine tumor for instance. The urethrovesical apparatus is not affected in the least. The patients are completely tranquil and in perfect condition during the day following the operation. The only incident is an exceptional vomiting, which may occur three or four times, about four hours after the intervention. During the afternoon or evening the most disagreeable and frequent incident, the headache, is liable to appear. Tuffier has observed it in 40 per cent. of his patients. It resembles migraine in character, but does not coincide with the vomiting, and in 90 per cent. was almost completely gone by the next morning. In 2 per cent. it was very severe and continued for two to four days, progressively subsiding. No remedy seems to control it, and he now merely applies a compress of cold water to the brow. In three patients a tardy cephalalgia appeared after two to five days of complete tranquillity, more annoying than strictly painful, gradually subsiding in the course of seven days. It is difficult to understand this cephalalgia, as the cocain disappears so rapidly from the cerebrospinal fluid that not a trace can be discovered an hour after the operation. There is no chemical irritation of the pia-arachnoid membrane; cytologic examination and tests of its permeability with iodin have demonstrated its integrity. The temperature rose in 45 per cent. to 37.8, 38 and 38.5, and exceptionally to 39 and 39.5 C. The curve in 50 patients was well defined and constant, commencing about four to six hours after the analgesia, attaining the maximum the eighth to tenth and returning to normal by the twelfth to fourteenth. It never persisted beyond the twentieth hour. The urine does not suggest in any respect the urine-formula of fever. The blood shows no alteration resembling the leucocytosis of fever. The elevation of temperature is probably due to the action of the cocain on the thermogenic centers. The subjective and other symptoms were never so severe as to cause any alarm. The age of his patients ranged from 10 to 79. but as a general thing he prefers not to use this method of analgesia on children and hysterics. Children bear the cocain very well, but are liable to become frightened. He believes that persons with heart affections or arteriosclerosis have nothing to fear from it, as he has cocainized a large number. For all extraperitoneal operations analgesia by the spinal route bears comparison with general anesthesia—the future will show whether it ought not to supplant the latter. In operations on the lung and pleura in the two lower-thirds of the thorax it is the method of election, as chloroform and ether have serious disadvantages in these conditions. In regard to intraperitoneal operations, he would not recommend the method unless the surgeon is thoroughly familiar with abdominal surgery. Everything is all right as long as no incidents happen—and this is the rule—but if vomiting or nausea occurs the operator, must wait for it to subside, and thus be hindered. In simple interventions, such as vaginal hysterectomy, ablation of the appendix or herniotomy, a little nausea is of no importance, but it may prove serious in operations on the liver, stomach or intestine, or in tedious interventions on the annexes or uterus.

Berliner Klinische Wochenschrift, December 3 and 10.

Treatment of Fractures of the Jaw. Warnekros.—For severe fractures of the jaw Warnekros has devised a splint which holds the parts in the correct position in the simplest manner, and can be removed for daily disinfection. It is merely a rubber plate made to fit over the jaw, allowing the teeth to protrude, such as dentists apply to correct the position of a tooth on the other jaw. It is small, light, aseptic, does not interfere with chewing or talking, and can be removed every day for disinfection of the plate and region after the third day. In one case the fracture was in the ascending branch of the lower jaw. A broad loop of stout gold wire projecting from the end of the rubber plate-cap supported the fractured portion to counteract the action of the external pterygoid muscle on the other side. In another case the upper jaw was fractured in three places and the lower jaw in one. The splints were taken out and disinfected every day and the fractures healed with no deformity.

December 10.

Cure of Hernia of the Lung. O. Vulpius.—Hernia of the lung developed consecutive to an unhealed fracture of the right third rib on a man of 42. He was able to reduce the hernia at first, but the frequent relapses caused irritation, catarrhal conditions and a cough. By the end of a year the hernia had become the size of two fists and operative intervention was imperative. Vulpius planned to slit the second and fourth ribs and fasten the outer half to the stump of the third rib, leaving the bone-flap still attached to the rib at its root. He accomplished this with the second rib, fastening the flap in a convex position, but the adhesions were too extensive for the operation to be completed on the fourth rib. The results were extremely satisfactory, even with this partial intervention.

Centralblatt f. Bakteriologie (Jena), November 30.

Diphtheria in the Horse. L. Corbett.—The genuine diphtheria bacillus was found in the secretions of a sick pony, the only source for the infection of a little girl that could be discovered. When diphtheria antitoxin is found in the serum of horses, therefore, it evidently has the same significance as when found in man.

The Filaria in the Mosquito. B. Grassi.—The fact that the filaria sanguinis is transferred to man exclusively by the mosquito seems to be established by the results of Grassi's research, which has determined that the larvæ of the filaria immitis enter the Malpighian bodies and there complete their development. In ten days they pass into the abdominal cavity and up to the head, accumulating in the prolongation of the cavity in the labium. From the labium they pass into the body of the animal stung. The filaria nocturna develops in the thoracic muscles. Both were found in several varieties of the anopheles and the immitis also in the culex penicillaris and pipiens.

Deutsche Med. Wochenschrift, (Leipsic), December 6 and 13.

Athyreosis in Children. H. Quincke.—Two cases are described in detail to sustain Quincke's assertions that we are still far from knowing all the variations of the clinical picture induced by defective and disturbed functioning of the thyroid gland. He thinks this condition should be classed with uremia and diabetes as an autointoxication, possibly multiple. In puzzling cases of tardy development, mental or physical, the possibility of an affection of the thyroid gland should not be overlooked, even when the typical symptoms of cretinism and myxedema are absent. These rudimentary and abortive cases are not only the most interesting, but they are the most amenable to thyroid treatment. In one of the cases described the growth was normal, although the other symptoms indicated sporadic cretinism, and the autopsy showed that the thyroid gland, which had been the size of a bean during the first year of life, had completely disappeared by the fourth year. In the second case the cretinism commenced to develop insidiously in an apparently normal child 15 months old. A peculiar feature of this case was that all the teeth but two dropped out. The symptoms suggested an organic cerebral lesion, but a few months of thyroid treatment cured the condition completely. He suggests the term "athyreosis subacuta" for these rudimentary cases.

December 13.

Testing for Knee-Jerk. Walbaum.—In testing dubious cases it is possible to detect even the slightest reflex action by placing the hand on the patient's knee, the fingers on the ligamentum patellæ inferius, while the thumb and tip of the little finger rest on the upper edge of the patella, the latter thus enclosed between the fingers and the palm. If the hand is then struck lightly with the other fist the fingers feel the ligament spring up if the knee-jerk is still present.

Finsen's Radiotherapy. S. Bang.—The ultraviolet rays are not absorbed in Finsen's radiotherapy, on the contrary they are exceptionally numerous and effective. He has succeeded in killing cultures of bacteria in one second, and Bang announces that with an ordinary, unconcentrated arc light it is possible to kill the prodigiosus in one minute or less, with a current of 34 amperes and 50 volts, at a distance of 38 cm.

Mitteilungen a. d. Grenzgeb. (Jena), vii, Nos. 2 and 3.

Anatomy of Hypertrophied Prostate. S. Ciechanovski.—Twenty-six pages of this extensive article are devoted to the bibliography of the subject, including many works by Slavonian writers. The author concludes that the hypertrophy is usually due to some inflammatory process which may have caused no symptoms at the time, and in the largest majority of cases, if not all, is of gonorrheal origin. A convincing argument in favor of this assumption would be the discovery that gonorrhea is restricted to man and dogs, as the hypertrophy of the prostate seems to be limited to them.

Influence of Artificially Induced Hyperemia on the Brain. A. Bier.—Constricting the neck with a rubber band hooked tight induces hyperemia of the brain, and Bier has established that it is not a dangerous procedure. He wore the band himself for five nights and, except for headache the first day, experienced no ill effects beyond the sleeplessness caused by the unusual sensation of the band. It was also tried on a number of patients in hopeless stages of tubercular meningitis in the attempt to supply the artificial congestion which Bier has found beneficial in other forms of tubercular affections. The effect of the constriction was also studied on a few patients with a defect in the skull, allowing the pulsation to be watched. He has established that abrupt application and removal of the band produces remarkable variations in the intracranial circulation. The next step was to apply these data to the treatment of epilepsy, and he reports ten cases thus treated. He found that the constriction was borne remarkably well by epileptics. When the band was applied so tight as to have caused throbbing and headache in Bier and others, the epileptics did not seem to experience anything of the kind and merely complained of the interference with swallowing. In six the seizures were diminished in number and intensity, including one patient who had had one or more every day for a year, and had no recurrence for six days after wearing the band for four. Several patients stated that the band arrested the distressing sensation of pressure and vertigo in the head. Three other patients were unaffected and in another the seizures seemed to last a little longer. In no case was a seizure ever induced by the constriction. It has proved effectual in warding off nervous headaches in another patient during the past year, applied at the premonitory symptoms. It also demonstrated an unmistakably beneficial influence on one of three cases of severe chorea thus treated. He observes that possibly the benefits attained by craniectomy in epilepsy are due merely to the hyperemia induced by the operation, as in cases of tubercular peritonitis. Lumbar puncture may also induce hyperemia in the brain as the blood rushes into the vacuum left by the removal of the cerebrospinal fluid.

Operative Treatment of Pericarditis. Reichard.—The prognosis depends upon the etiology, Reichard concludes from study of thirty-three cases. The favorable termination in two exceptionally severe cases of purulent traumatic pericarditis speaks emphatically in favor of operative intervention in such circumstances. The majority also recover in other cases of primary affection and pericarditis consecutive to pleuritis and empyema, but after influenza, pneumonia and severe osteomyelitis it is nearly always fatal.

Total Necrosis of the Testicle from Mumps. A. Stolz.—A very slight attack of mumps in a young man of 18 was followed by painful swelling of the left testicle, terminating in total, isolated necrosis.

Muenchener Med. Wochenschrift, December 11.

Relations Between Rhodan in Saliva and Iodin Intoxication. O. Muck.—The writer has been making a study of the results of injury of the innervation of the salivary glands from chronic otitis of the middle ear. In the course of this research he has discovered that persons with an unusual amount of rhodan in the saliva are exceptionally liable to acute iodism in consequence of ingestion of even moderate amounts of potassium iodid. Almost invariably symptoms of iodism appeared, varying from iodin acne to general nausea, while patients with a transient or permanent lack of rhodan in the saliva bore the potassium iodid without disturbance.

Chloral and Hemorrhages. A. MODEL.—The writer suffered for years from threatening hemorrhages from stomach, intestines, lungs and nose, which were finally traced to the moderate use of chloral for insomnia, and have ceased since the drug has been completely abandoned. The case is not pure, as latent atheromatosis exists and father and brother also manifest a slight hemorrhagic diathesis.

Wiener Klinische Wochenschrift, December 13.

Schleich's Local Anesthesia. F. V. FRIEDLAENDER.—This communication from the late Professor Albert's clinic summarizes the indications for this method of anesthesia as deduced from long experience: all operations on the skin, even protracted plastic operations, and all operations for which general narcosis is contraindicated. It is relatively indicated also in the so-called typical operations on the extremities if the intervention can be completed without toxic doses of cocain, and also for operations on the intestines when they can be performed without pulling, when there is no inflammation of the peritoneum and when palpation of the abdominal cavity can be dispensed with.

Dietetic Treatment of Hyperacidity. E. V. SOHLERN.—In the writer's long experience at Kissingen he has found that the majority of persons with hyperacidity not only tolerate certain carbohydrates, but that the latter are important factors in the cure. They must be easily digestible, non-stimulating to the secretions, soft like porridge and not too concentrated. Potato, for example, can be eaten by nearly every hyperacid person without disturbance if mashed, put through a sieve and then stewed with milk.

Gazzetta Degli Ospedali (Milan), December 9.

The Blood in Animals After Ablation of Thymus. A. COSENTINO.—A marked and progressive hyperleucocytosis was noted in rabbits and dogs after removal of the thymus and, parallel with it, an increasing bactericidal power of the serum, reducing the number of colonies from 155 and 552, for instance, to zero in forty-eight hours.

The Blood of Subjects With Carcinoma. DARIO MARAGLIANO.—Careful tests and experiments with the blood of thirty-three persons with carcinoma of the uterus, mammæ, stomach or other organs failed to reveal any blastomycetes or parasites such as have been described by Bra, Chevalier and others, although the conditions of the tests were scrupulously identical.

Intraspinal Resection of the Posterior Roots for the Cure of Rebellious Sciatica. D. GIORDANO.—A man of 26 with recurring sciatica of such severity that work was impossible, and the patient could not use his limb, was temporarily cured by stretching the nerve. When the neuralgia recurred Giordano yielded to the patient's appeals for relief and resected the posterior roots of the nerve, after exposing the eleventh and twelfth dorsal and first lumbar vertebræ. The dura was sutured with catgut and the flap replaced, leaving a small drain. All sensibility in the member was abolished and the patient could use his limb at once as he had not been able to use it for months. The second day acute pain was felt along the internal saphenous nerve, which proved rebellious to treatment and was finally cured by resecting this nerve below the tuberosity of the tibia, eight days after the primary operation. During the months that have elapsed since there have been no traces of pain. No trophic disturbances have been noted and the member is gradually recovering the sense of contact and pain on external irritation.

St. Petersburg Med. Wochenschrift, December 8.

Spontaneous Evacuation of Extrauterine Pregnancy. A KUPFFER.—In the case described a woman of 53 evacuated per anum the bones of a fetus from an extrauterine pregnancy ten years before. The bones accumulated twice in the rectum, causing intense pain. Eleven cases are on record of a similar spontaneous irruption of remains of the extrauterine fetus into the intestines.

Change of Address.

C. J. Aldrich, 744, to 612 Prospect St., Cleveland, Ohio.
J. S. Blackburn, 41 Michigan Ave., to 1141 Hudson Ave., Detroit.
S. A. Bonnaffon, Williamsport, to 3439 Walnut St., Philadelphia, Pa.
J. T. Bunting, Harrisburg, to 114 S. 5th St., Reading, Pa.
F. W. Bates, Ft. Worth, Tex., to Hot Springs, Ark.
O. B. H. Bowser, Richmond, Va., to 2226 11th St., N. W., Washington, D. C.
F. F. Bryan, Georgetown, Ky., to Newberry Hotel, Chicago.
J. H. Coughlin, 303, to 307 E. Broadway, New York City.
H. M. Farney, Kansas City, Mo., to Mound City, Kan.
D. F. Grasse, Dickey, N. D., to Garrison, Iowa.
C. E. Hillis, 66 N. 2nd St., to 108 N. 3rd St., Memphis, Tenn.
C. P. Hough, Salt Lake City, Utah, to 224 Miller St., Jefferson City, Mo.
M. J. Levitt, 253 E. 105th St., to 1757 Madison Ave., New York City.
Lydia H. LaBaume, Rockford, to Batavia, Ill.
T. B. Morrissey, Chicago, to 126 N. Avon St., Rockford, Ill.
J. J. Minot, Mattapan, Mass., in care Mrs. Doulton, Box 1606 Santa Barbara, Cal.
A. D. Van Dyke, Baltimore, Md., to Marysville, Pa.
E. H. Moore, New York City, to Whitehouse Station, N. J.
F. H. Martin, Milwaukee, to Edgerton, Wis.
B. W. Macfarland, Bordentown, to Trenton, N. J.
G. Maxwell, Haldane, Ill., to Watonga, O. T.
H. J. Prentiss, 852 W. End Ave., to 239 W. 103rd St., New York City.
J. G. Pope, Rockwood, to Coleman, Tex.
M. Pritchard, Sierra Valley, to Sierraville, Cal.
Rev. J. A. Rudolph, 214 E. Randall St., to 209 E. Fort Ave., Baltimore, Md.
H. Rees, Preston, Minn., to Walcott, N. D.
M. W. Richardson, 10 Exeter St., to Equitable Bldg., Boston, Mass.
A. B. Richardson, Massillon, Ohio, to Government Hospital for Insane, Washington, D. C.
F. P. Shelby, Shelby, to Deeson, Miss.
S. C. Sims, 56 N. 3rd St., to 50 N. 4th St., Memphis, Tenn.
W. F. Seymour, Reedsburg, Wis., to 458 W. Adams St., Chicago.
F. L. Wilcox, Albert Lea, to Walker, Minn.
B. J. Wadey, Belleville, to 218 W. Madison St., Belvidere, Wis.
J. P. Welch, Aultman, Ariz., in care Dr. R. J. Rowland, Troupe, Texas.

Queries and Minor Notes.

CALL OF COURTESY.

SANDY, UTAH, Dec. 28, 1900.

To the Editor:—Should a new physician, just locating, call first upon brother practitioners, or is it the other way? DR. C. E. B.

ANS.—See reply to B. C. K., page 71, THE JOURNAL, of last week.

COST OF A COURSE IN EDINBURGH.

PORT TAMPA CITY, FLA., Dec. 18, 1900.

To the Editor:—Will you please inform me what would be the approximate expenses of a trip to Europe—with taking a course of lectures. I desire to go to Edinburgh, and if you can put me in communication with the University I would be glad. Yours very truly, J. M. G.

ANS.—The fare across the Atlantic can be made comparatively low on some lines, the American Line from Philadelphia to Liverpool for example, which gives a comfortable passage for $38 over, in the winter, and $31 returning at same season of year. The additional expense of railroad fare to Edinburgh and return to Liverpool would be $10 or less. About $5 to $10 per week will pay for comfortable board and lodging, and the fees for lectures are from $5 to $20 per class or course. If the passage over or back is in the summer season the rates are higher, perhaps $10 more. A letter addressed to the Dean of the Faculty of Medicine, University of Edinburgh, would obtain the further details needed.

MEDICAL PRACTICE ACTS.

PHOENIX CITY, ALA., Dec. 28, 1900.

To the Editor:—What are the regulations governing the practice of medicine in the State of Florida? W. L. M.

ANS.—A diploma and examination are required. The examining boards are separate for each judicial district of the state.

RICHMOND, IND., Dec. 29, 1900.

To the Editor:—Will you please inform me through THE JOURNAL what the laws are in Missouri, Arkansas and Texas for the practice of medicine, and oblige. J. B. L.

ANS.—Arkansas requires an examination before the county board of examiners. The license given is good as long as residence in that county continues. The fee is $6. In Missouri a diploma properly verified is required. In Texas an examination by special examining boards in the different judicial districts is provided for, but the law, however, is very lax, and a diploma is said to be practically all that is required; one diploma is as good as another, according to a decision of the Supreme Court. It is likely there will soon be some further legislation rendering conditions more strict.

A CLINICAL STUDY OF ONE HUNDRED AND FIFTY CASES OF HYPERPHORIA.*

WENDELL REBER, M.D.,
PHILADELPHIA.

When this paper was first thought of, I went over all my records with a view of finding in what percentage of cases hyperphoria had been noted; also what lessons were to be derived from the study of these cases. After much examination I decided to limit myself to my last 700 cases, throughout which there has been almost absolute uniformity of study. The statistics resulting from any study of these 700 records will therefore be of much greater interest and more faithful to the facts than had I included my preceding 1700 records, many of which are more or less incomplete as to the muscular status.

In every case painstaking correction of all refractive errors was made, the tests for hyperphoria preceding and following the refraction. Out of these 700 records 525 were refraction cases, in every one of which the muscular status was carefully estimated with the Maddox rod—and sometimes with supplementary methods—before giving the prescription. It is my conviction that without full knowledge of the muscular status, it is absolutely impossible to come to an intelligent conclusion as to what lenses ought to be ordered in any given case of ametropia.

Hyperphoria is spurious or intrinsic. The former is almost invariably an outward expression of perverted accommodation. In such cases where the ciliary muscle has been cured of its bad habits by a mydriatic or the wearing of proper correcting lenses, the vertical deviation usually disappears. Particularly is this true when oblique astigmatism has been the fault. Moreover, lithemia, gout, neurasthenia and, I have sometimes thought, early tabes, will at times produce a transient hyperphoria which might easily lead the examiner astray if the general economy and the patient's life habits are not kept constantly in view.

Intrinsic hyperphoria, on the other hand, is uninfluenced by a mydriatic. Indeed in some cases I have seen a small but gradual daily increase under prolonged cycloplegia. This is no less true after wearing a proper correction, for, as far as my experience goes, intrinsic hyperphorias are little if any influenced by curing the ciliary muscle of its vicious habits. True, many such patients will be entirely relieved of all their symptoms by assuming the proper correcting glasses, in which case treatment directed to any coincident muscular imbalance is meddlesome ophthalmology. But, on the other hand, I have known people to wear perfect corrections for some years, going from one to another ophthalmologist, still seeking relief, only to find it when a vertical prism had been combined with their curvature correction.

Whether a patient shall or shall not receive a prism correction should be entirely a matter of symptoms. Some people carry a vertical imbalance of 1 to 2 degrees all through a life of high tension and large usefulness without the slightest discomfort, while in others .5 to .75 degree is sufficient to make life an almost intolerable burden. Into this phase of the question enter such factors as heredity, temperament, life habits, worry, and all the rest of that intricate aggregation of facts that go to make up the personality of our patients.

But there seems a degree of hyperphoria below which it is trivial to go, and this I would fix at .5 degree—tentatively at least. Nothing less than this was recognized in the 700 records studied.

In the early part of my muscle work the diplopia test was unfailingly applied, either by means of a single rotary prism or the Stevens phorometer. But I soon found myself relying on the Maddox rod, and for the very good reason—shown by my colleague, Dr. Hansell—that any test that compared the behavior of a foveal image of one eye with a perifoveal image of the other eye could not but often lead the surgeon into false conclusions; this is because of the stimulation of non-corresponding points in the two retinas. The test that would so deform one image as to temporarily set aside the fusion impulse, and at the same time allow a certain portion of this deformed image to fall on the fovea of the eye seeing that image, certainly seems the best test so far at our command—hence the great value of the Maddox rod. On this test I have rested the diagnosis in these 150 cases.

There is a diplopia test that is of signal value in the detection of hyperphoria, namely, the use of a colored glass to detect, if possible, spontaneous diplopia, which if found is of great significance. But this is natural diplopia conforming to the proposition that a test must concern both foveæ centrales; hence this diplopia test is free from the objections made against those tests based on artificially produced diplopia.

Latent Hyperphoria.—An interesting feature in connection with this study is that out of the 150 times in which hyperphoria was found, it was partially or wholly latent in 49—or practically 33 per cent.—of the times it occurred. In glancing over the methods of various workers for the unmasking of latent hyperphoria I find that all of them are some manner of modification of the "blinder" test. It is now a fairly well accepted fact that in a certain number of cases, if a blinder is worn before one eye for fifteen to thirty minutes, a hyperphoria varying from .5 to 1 degree will often show itself for a few minutes after uncovering the eye.

---

* Presented to the Section on Ophthalmology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Dec. 20 to 26, 1900, inclusive:

Frederick S. Dewey, captain and asst.-surgeon, 38th Vol. Infantry, honorably discharged from the service of the United States, to take effect February 20, 1901.

Gerry S. Driver, acting asst.-surgeon, from Washington, D. C., to Chicago, Ill., for temporary duty as examiner of recruits.

William R. S. George, acting asst.-surgeon, from Washington, D. C., to Governor's Island, N. Y., for assignment to duty at San Juan, P. R.

Thomas W. Jackson, acting asst.-surgeon, from temporary duty at the U. S. Military Academy at West Point, N. Y., to San Francisco, Cal., for duty with troops going to Manila and subsequent assignment in the Division of the Philippines.

William C. LeCompte, acting asst.-surgeon, from San Juan, P. R., to Washington, D. C., to report to the Surgeon-General for instructions.

Joseph C. Reifsnyder, acting asst.-surgeon, relieved from further duty in the Division of the Philippines and assigned to duty at the U. S. Military Academy at West Point, N. Y.

Henry A. Webber, lieutenant and asst.-surgeon, U. S. A., leave of absence from the Department of Eastern Cuba extended.

Navy Changes.

Changes in the Medical Corps of the Navy for week ending Dec. 29, 1900:

Asst.-Surgeon R. E. Ledbetter, detached from the *Monongahela* and ordered to the *Constellation.*

Asst.-Surgeon C. R. Burr, orders of Dec. 19 revoked, and to resume duties on the *Monongahela.*

Medical Director G. P. Bradley, commissioned medical director from May 31, 1900.

Medical Director P. Fitzsimons, commissioned medical director from Nov. 19, 1900.

Surgeon G. H. Barber, commissioned surgeon from June 7, 1900.

Asst.-Surgeons S. S. Rodman and J. M. Brister, appointed from Dec. 14, 1900.

DIED.

Medical Inspector W. H. Jones, retired, died at Bethlehem, Pa., Dec. 13, 1900.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service, for the seven days ended Dec. 27, 1900:

Surgeon W. P. McIntosh, to proceed to Columbus, Georgia, for special temporary duty.

Asst.-Surgeon C. E. Decker, granted leave of absence for 14 days on account of sickness.

Asst.-Surgeon L. P. H. Bahrenburg, relieved from duty at the Immigration Depot, New York City, and directed to proceed to Manila, P. I., and report to the chief quarantine officer for duty.

Acting Asst.-Surgeon Francis Duffy, granted leave of absence for six days from December 29.

Acting Asst.-Surgeon W. J. Linley, granted leave of absence for thirty days.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Dec. 28, 1900:

SMALLPOX—UNITED STATES.

Florida: Jacksonville, Dec. 2, 1 case.
Kansas: Wichita, Dec. 15-22, 10 cases.
Kentucky: Lexington, Dec. 22, 1 case.
Maryland: Baltimore, Dec. 22, 1 case.
Minnesota: Dec. 15-22, Minneapolis, 12 cases; Winona, 120 cases.
New Hampshire: Manchester, Dec. 15-22, 14 cases.
New Jersey: Jersey City, Dec. 16-23, 7 cases.
New York: New York, Dec. 15-22, 21 cases.
Ohio: Ashtabula, Dec. 15-22, 15 cases; Cleveland, Dec. 15-22, 25 cases; Portsmouth, Dec. 22, 1 case.
Tennessee: Memphis, Dec. 22, 1 case.
Texas: Houston, Dec. 15-22, 22 cases, 1 death.
Utah: Salt Lake City, Dec. 15-22, 31 cases.
Washington: Tacoma, Dec. 15, 1 case.
Wisconsin: Milwaukee, Dec. 22, 1 case.

SMALLPOX—FOREIGN.

Argentina: Buenos Ayres, Sept. 30, 7 cases, 6 deaths.
Bohemia: Prague, Nov. 24-Dec. 1, 43 cases.
Brazil: Pernambuco, Oct. 1-15, 26 deaths; Rio de Janeiro, Oct. 1-31, 69 deaths.
Egypt: Alexandria, Nov. 27, 3 cases 1 death.
England: London, Dec. 1-8, 1 case.
France: Paris, Dec. 1-8, 14 deaths.
India: Calcutta, Nov. 17, 6 deaths.
Mexico: Mexico, Dec. 16, 1 case, 2 deaths; Progreso, Dec. 9-15, 3 cases.
Russia: Nov. 24-Dec. 1, 9 cases; Warsaw, 36 deaths.
Scotland: Glasgow, Dec. 7-14, 58 cases, 1 death.

YELLOW FEVER.

Brazil: Rio de Janeiro, Oct. 1-31, 31 cases, 6 deaths.
Mexico: Vera Cruz, Dec. 14, 2 deaths.

CHOLERA.

India: Bombay, Nov. 13-20, 3 deaths; Calcutta, Nov. 10-17, 26 deaths; Madras. Nov. 9-16, 7 deaths.
Straits Settlements: Singapore, Nov. 10-13, 5 cases, 5 deaths.

PLAGUE.

Brazil: Petropolis, Dec. 10, 1 death; Rio de Janeiro, Oct. 1-31, 31 cases, 20 deaths.
India: Calcutta, Nov. 17, 2 deaths.
Japan: Osaka, Nov. 2-27, 8 cases, 8 deaths.
Madagascar: Tamatave, Nov. 11, 1 case.

THE JOURNAL OF THE
AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage, $2.50. Subscriptions may commence at any time. Volumes begin with the first issue of January and of July.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

The qualifications for membership require that the applicant be a member, in good standing, of a state or local medical society entitled to send delegates to the annual meeting of the American Medical Association. A list of these societies will be sent on request. Applications must be accompanied with a certificate showing that the applicant is a member of a recognized society, and should be sent with the annual dues—five dollars—to the treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago. Members receive The Journal free. Subscribers to The Journal may become members of the Association without additional expense if they are members of medical societies recognized by the Association. Those desiring to have their names transferred from the subscription to the membership lists should send certificates as above, with a receipt for their subscription to The Journal, covering the current fiscal year.

FISCAL YEAR.

The fiscal year of the American Medical Association is from January 1 to December 31; and the annual dues paid by a new member cover only the fiscal year, no matter at what time of year the membership is obtained. Those who pay their dues and join the Association at the annual meeting in June, for instance, pay only for the fiscal year which ends with the December following, and the annual dues for the following fiscal year are payable the succeeding January, at which time the treasurer sends a statement to each member. Such members, however, are entitled to The Journal for the full year, even though the membership be not continued.

PAPERS READ AT THE ANNUAL MEETING.

"Every paper received by this Association and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the Association. . . The Board of Trustees shall have full discretionary power to omit from the published transactions, in part or in whole, any paper that may be referred to it by the Association or either of the Sections, unless specially instructed to the contrary by vote of the Association." (From Article V of the By-laws.)

NEWS.

Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

ORIGINAL PAPERS.

Articles are accepted for publication with the understanding that they are contributed solely to this journal.

COPYRIGHT.

Matter appearing in The Journal of the American Medical Association is covered by copyright, but as a general thing, no objection will be made to the reproduction of anything appearing in its columns if proper credit be given.

CONTRIBUTIONS TYPEWRITTEN.

It will be satisfactory to all concerned if authors will have their contributions typewritten before submitting them for publication. The expense is small to the author—the satisfaction is great to the editor and printer. We can not promise to return unused manuscript.

Half-tones, zinc etchings and other illustrations will be furnished by The Journal when photographs or drawings are supplied by the author.

ADVERTISEMENTS.

Advertising forms go to press eight days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. Advertising rates will be made known on request.

CHANGE OF ADDRESS.

In ordering a change of address it is important that both the old and new addresses be given.

REMITTANCES.

Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "Journal American Medical Association," except those for annual dues. These should be made payable and sent direct to the Treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago.

A CLINICAL STUDY OF ONE HUNDRED AND FIFTY CASES OF HYPERPHORIA.*

WENDELL REBER, M.D.,
PHILADELPHIA.

When this paper was first thought of, I went over all my records with a view of finding in what percentage of cases hyperphoria had been noted; also what lessons were to be derived from the study of these cases. After much examination I decided to limit myself to my last 700 cases, throughout which there has been almost absolute uniformity of study. The statistics resulting from any study of these 700 records will therefore be of much greater interest and more faithful to the facts than had I included my preceding 1700 records, many of which are more or less incomplete as to the muscular status.

In every case painstaking correction of all refractive errors was made, the tests for hyperphoria preceding and following the refraction. Out of these 700 records 525 were refraction cases, in every one of which the muscular status was carefully estimated with the Maddox rod—and sometimes with supplementary methods—before giving the prescription. It is my conviction that without full knowledge of the muscular status, it is absolutely impossible to come to an intelligent conclusion as to what lenses ought to be ordered in any given case of ametropia.

Hyperphoria is spurious or intrinsic. The former is almost invariably an outward expression of perverted accommodation. In such cases where the ciliary muscle has been cured of its bad habits by a mydriatic or the wearing of proper correcting lenses, the vertical deviation usually disappears. Particularly is this true when oblique astigmatism has been the fault. Moreover, lithemia, gout, neurasthenia and, I have sometimes thought, early tabes, will at times produce a transient hyperphoria which might easily lead the examiner astray if the general economy and the patient's life habits are not kept constantly in view.

Intrinsic hyperphoria, on the other hand, is uninfluenced by a mydriatic. Indeed in some cases I have seen a small but gradual daily increase under prolonged cycloplegia. This is no less true after wearing a proper correction, for, as far as my experience goes, intrinsic hyperphorias are little if any influenced by curing the ciliary muscle of its vicious habits. True, many such patients will be entirely relieved of all their symptoms by assuming the proper correcting glasses, in which case treatment directed to any coincident muscular imbalance is meddlesome ophthalmology. But, on the other hand, I have known people to wear perfect corrections for some years, going from one to another ophthalmologist, still seeking relief, only to find it when a vertical prism had been combined with their curvature correction.

Whether a patient shall or shall not receive a prism correction should be entirely a matter of symptoms. Some people carry a vertical imbalance of 1 to 2 degrees all through a life of high tension and large usefulness without the slightest discomfort, while in others .5 to .75 degree is sufficient to make life an almost intolerable burden. Into this phase of the question enter such factors as heredity, temperament, life habits, worry, and all the rest of that intricate aggregation of facts that go to make up the personality of our patients.

But there seems a degree of hyperphoria below which it is trivial to go, and this I would fix at .5 degree—tentatively at least. Nothing less than this was recognized in the 700 records studied.

In the early part of my muscle work the diplopia test was unfailingly applied, either by means of a single rotary prism or the Stevens phorometer. But I soon found myself relying on the Maddox rod, and for the very good reason—shown by my colleague, Dr. Hansell—that any test that compared the behavior of a foveal image of one eye with a perifoveal image of the other eye could not but often lead the surgeon into false conclusions; this is because of the stimulation of noncorresponding points in the two retinas. The test that would so deform one image as to temporarily set aside the fusion impulse, and at the same time allow a certain portion of this deformed image to fall on the fovea of the eye seeing that image, certainly seems the best test so far at our command—hence the great value of the Maddox rod. On this test I have rested the diagnosis in these 150 cases.

There is a diplopia test that is of signal value in the detection of hyperphoria, namely, the use of a colored glass to detect, if possible, spontaneous diplopia, which if found is of great significance. But this is natural diplopia conforming to the proposition that a test must concern both foveæ centrales; hence this diplopia test is free from the objections made against those tests based on artificially produced diplopia.

Latent Hyperphoria.—An interesting feature in connection with this study is that out of the 150 times in which hyperphoria was found, it was partially or wholly latent in 49—or practically 33 per cent.—of the times it occurred. In glancing over the methods of various workers for the unmasking of latent hyperphoria I find that all of them are some manner of modification of the "blinder" test. It is now a fairly well accepted fact that in a certain number of cases, if a blinder is worn before one eye for fifteen to thirty minutes, a hyperphoria varying from .5 to 1 degree will often show itself for a few minutes after uncovering the eye.

---

* Presented to the Section on Ophthalmology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Some surgeons still resort to this method for the detection of supposed latent hyperphoria. Posey has modified this method by first working out the correction of the right eye and then with the correction still before that eye placing in front of it a blank disc. The left eye is now examined, and when the proper correction has been worked out, the Maddox rod is placed before the left eye. He now lifts the blank disc from in front of the right eye which has thus been under cover for from five to ten minutes. If latent hyperphoria exists, it is likely to show itself wholly or in part by this unveiling test.

My own maneuver differs but slightly from Posey's method. After the right eye has been corrected, I place in front of the correction the Maddox rod. When the left eye has been corrected, I immediately direct the patient's attention to the streak of light and after carrying the streak several times from the vertical to the horizontal position, have them tell me its relation to the point of light. I believe that by having the patients fix their attention on the streak in the vertical position and then suddenly swinging it into the horizontal position, the higher cerebral centers are taken by surprise and the detection of latent hyperphoria made relatively easy. The rod should be reversed a dozen times or more, each time questioning the patient as to the relative positions of the streak and light. The purpose is twofold: 1, by continually throwing the higher centers off their guard to unveil more of the hyperphoria; 2, frequent repetitions of the maneuver to educate the patient to assist in the determination by relaxing the impulse to binocular fixation as we relax the accommodation.

Any method that takes the higher centers off their guard will reveal the deviation. Binocular single vision is one of the brain's most complicated automatic functions. It concerns a cerebral—or governing—and a peripheral—or executing—apparatus in the most intimate association. The unconscious preservation of binocular single vision is so deeply rooted a thing in the human automatism that something. some trick, is needed that will temporarily set aside the dominating influence of the cortical centers over the eyeballs and their muscles. Only in this way can latent deviation tendencies in the peripheral portion—the eyeballs—of the binocular vision apparatus be revealed in many cases —and especially in young subjects.

Age seems to play no small part in this matter, for hyperphoria is much more commonly manifest after 40 years of age than before that time. It is difficult to put down the thought that along with the loss of ciliary elasticity there goes a similar loss of compensating elasticity in the extraocular musculature, that favors the easier detection of any previously existing lateral or vertical deviations. Certain it is that in presbyopes, hyperphoria is much more easily shown and vertical prisms are much more comfortably worn than by the generality of young people. In only 7 cases out of these 150 was hyperphoria found before the 20th year.

Between the 20th and 30th years hyperphoria occurred in 34 cases; 30th and 40th years, 50 cases; 40th and 50th years 29 cases; 50th and 60th years, 27 cases; after the 60th year 3 cases. These figures refer to true hyperphorias only, in whom binocular vision was invariably present. No instance of actual vertical squint was allowed to creep in.

As to the refraction conditions with which hyperphoria is associated, it was encountered 117 times out of 150 in hypermetropia and hypermetropic astigmatism; 17 times in myopia and its allied states; 8 times in mixed astigmatism; 6 times in antimetropia—commonly termed anisometropia—and twice in emmetropia. Anisometropia has not in my experience furnished the large percentage of hyperphorias noted by some other workers in this field. Perhaps this is because I found actual vertical squint not infrequent among this class—in other words the findings do not differ in kind but in degree.

In its relation to lateral muscular deviations, the hyperphoria in these 150 cases was associated with esophoria 86 times, with exophoria 55 times, and with lateral balance 9 times. This too is easily explainable on the basis of the predominance of hypermetropia as above shown.

In 73 cases the upward deviation occurred in the right eye and in 77 in the left, so that there is practically no difference in the frequency with which either eye deviates.

Hyperphoria.	No. of times found.	Corrected with prism.	No prism correc.
½ degree	40	12	28
¾ degree	31	20	11
1 degree	43	35	8
1¼ degrees	3	3	—
1½ degrees	10	8	2
2 degrees	10	8	2
3 degrees	4	2	2
4 degrees	5	5	—
5 degrees	4	4	—
	150	96	54

The results of prism correction were the following: Number of cases, 96; good, 78; improved, 6; no change, 6; unknown, 6. In the 54 cases in which no prism correction was ordered the results were fairly good. Prism corrections were not ordered in these 54 cases, 1, because, notwithstanding the existence of unmistakable hyperphoria, the patient had been previously wearing either no correction or a wrong one; 2, because convergence-training or repression dissipated the symptoms; or 3, because the patient took such high power plus or minus lenses as to make inadvisable the incorporation of any vertical prism. Such patients learn readily but unconsciously to correct their hyperphorias, generally by tilting one lens a little higher than the other. In prescribing these 96 vertical prisms, full corrections were ordered in 20 cases, three-quarter corrections in 60 cases, and half of the deviation was corrected in 16 cases. Full corrections were made only in glasses for near work, because hyperphoria is generally greater for the occupation distance than for infinity, and experience has shown that the prism that fully corrects the deviation for infinity can often be comfortably worn in all near work. This observation is almost invariably true for hyperphoria of .75 degree or more.

My figures show further that in 40 cases which I have been enabled to follow, the hyperphoria has increased from 33 to 50 per cent. after six-months wear of a vertical prism. I have no explanation to offer for this increase, or rather unmasking of a latent hyperphoria. I can but point to what seems to me a perfect parallel; i. e., the uncovering of a latent hypermetropia by age. When some member of this Section has discovered and made practical, the use of a myoplegic that will paralyze the extraocular muscles as a mydriatic does the intraocular muscles, we shall have made a giant stride toward solving the physiology of the extraocular muscles in particular and the act of binocular vision in general. True, it would probably upset many of our pet notions of to-day and require us to build up new standards, but it would certainly give us some precious information as to the anatomic and functional positions of rest of the eyes.

The principal symptoms of vertical deviation tendencies are one-sided supraorbital, temporal and occipital neuralgias, photophobia, drowsiness, and tremendously exaggerated general fatigue after prolonged near work. I have been especially impressed with this last symptom in many cases. Too, hyperphoria stands in close relation, etiologically, to migraine; quite as close, I am sure, as oblique astigmatism.

In the effort to make hyperphorics comfortable without vertical prisms or tenotomies, too much attention can not be given to convergence deficiency or excess, the former to be met with convergence training after the method popularized by Gould, the latter with convergence-repression treatment by crowding on excessively strong convex lenses for ten-minute periods of work at the near point three or four times a day. These measures often suffice to wipe out all the symptoms. Moreover, as pointed out by Oliver,[1] sleep and exercise are splendid adjuncts in relieving the conditions of asthenopic hyperphorics. A few additional hours of sleep daily often rid a patient of much eyestrain that lenses, prisms, or tenotomies never fully reach. The benefit of exercise in the open is too patent for comment.

Tenotomy.—Out of the 150 cases studied, tenotomy was resorted to in only 5, all of which presented hyperphoria of 3 degrees or more. In no one of these 5 cases was there any marked difference in the refraction of the two eyes. Two were epileptics. One of them—a young man with left hyperphoria of 4.5 degrees—has been entirely free of epileptic manifestations for six months, whereas he had been having seizures daily. For three years he had worn a perfect correction of his low-grade ametropia without any effect on his minor epilepsy. In his case, I tenotomized the left superior and the right inferior rectus at the same sitting, securing 1 degree of overcorrection, which righted itself in four or five days. He has now absolute muscle balance.

The other, a 31-year-old married woman, has had but three epileptic seizures in four months, as against bi-weekly and sometimes tri-weekly attacks prior to operation. Her hyperphoria was 4 degrees.

The three remaining cases all presented distressing head symptoms not relieved by vertical prisms, but markedly benefited by free tenotomy of the superior rectus of the eye with the higher visual axis.

From the foregoing, the rational treatment of hyperphoria would seem to resolve itself into: *a*, wearing a proper correction four to six months; *b*, exclusion of causative diathesis or central nervous disease; *c*, convergence-training, if convergence be weak; *d*, convergence-repression, if convergence be excessive; *e*, if the hyperphoria is still annoying, prism correction of one-half to two-thirds of the vertical deviation for distance, and two-thirds to all of the deviation for near work; *f*, if the hyperphoria continues to produce urgent symptoms in spite of the preceding measures, tenotomy of the overacting elevators of one eye or the depressors of the other eye finally becomes justifiable.

Much more could be said in comment on the facts growing out of this study, but I shall have to content myself with recording the following convictions:

1. Hyperphoria occurs in about 1 out of 6 patients who seek counsel of the ophthalmologist.
2. It is present to the extent of .5 degree or more in 1 out of 3 refraction cases.
3. It becomes worthy of special attention in about 1 out of 5 refraction cases.
4. It is more likely to be latent before the 30th year—33 per cent. of all cases—and manifest after that time.
5. It occurs most frequently to the extent of about 1 degree.
6. The most frequent symptoms are supraorbital, temporal, and occipital neuralgias, photophobia, drowsiness, and abnormal physical tire after prolonged near work.
7. A full quota of sleep, daily open-air exercise, and a well-regulated life are all highly important factors in trying to make hyperphorics comfortable.
8. Hyperphoria is found a little oftener associated with esophoria—57 per cent.—than with exophoria—37 per cent. This is probably because compound hyperopic astigmatism with its associated convergence-excess outnumbers all other anomalies of refraction.
9. Convergence-training—if convergence be insufficient—and convergence-repression—if convergence be excessive—frequently relieve hyperphoric symptoms entirely.
10. *The vertical prism has a field of pronounced usefulness.*
11. Prism corections will be of service in about 50 per cent. of all cases. One-half to two-thirds of the hyperphoria may be corrected for infinity and two-thirds to the full amount for work at the occupation distance.
12. When all these means have been exhausted, section of some one of the vertical muscles may be thought of. About 1 out of 20 hyperphorics whose deviation is 2 degrees or more will profit more by tenotomy than by any other treatment. Two or three degrees is likely to be the amount permanently obtained by vertical tenotomy.
13. The only fruit that can be borne of the attempt at hospital or dispensary treatment of hyperphoria—or for that matter any but the simplest muscular anomalies—is vanity and vexation of spirit.

1212 Spruce Street.

DISCUSSION.

DR. H. F. HANSELL, Philadelphia—Dr. Reber's paper is a conclusive one based on experience and is a most conservative expression of opinion founded upon a careful, thorough, clinical investigation. The subject is a very large one and open to discussion in various ways, but the part that seems to me to have the greatest weight is the diagnosis of hyperphoria. The paper is valuable, too, in that the author has carefully excluded hypertropia. Many writings on this subject are complicated and rendered less valuable because there has not been a close line drawn between hyperphoria and hypertropia. The conditions are different; in the one case we are exercising our brain, musqular force and all the nerve energy we can to cancel the defect, and in the other case we have yielded to this defect, and the main symptom we get is diplopia, readily corrected by simply covering one eye, whereas the mental symptoms of hyperphoria, which make it such an important part of our practice, can only be relieved by a careful study and a great deal of practical clinical experience.

DR. MARK D. STEVENSON, Akron, Ohio—Like most ophthalmologists I used to test for hyperphoria with the Maddox rod and prisms immediately after the patient had left the dark room, but now I not only make these tests before finding the refraction of the eye, but also with the proper lenses before the eyes and a Maddox rod before one; then by alternately covering and uncovering the eye which does not have the Maddox rod before it I can discover many cases of hyperphoria. Many cases of latent hyperphoria can be discovered by simply rotating the

[1] Norris and Oliver: System of Diseases of the Eye.

Maddox rod from the vertical to the horizontal positions as suggested by Dr. Reber.

DR. G. C. SAVAGE, Nashville—Any muscle test that places the false images within the area of binocular fixation is full of error. The false image should be thrown entirely out of the area of binocular fixation and then we can at once get at the true condition. Monocular tests alone are trustworthy. Let me say that the hyperphoria which is corrected by convex lenses is a hyperphoria that is not due to any trouble in the superior or inferior recti, but is caused by error of attachment of the internal recti; the one muscle is simply attached too high, and the other too low. The esophoria you find in such cases is not an intrinsic esophoria, but a pseudo-esophoria. You correct the hypermetropia and at the same time cure the pseudo-esophoria and the hyperphoria disappears. Again the hyperphoria that is relieved by cylindrical correction is not due to any trouble in the superior or inferior recti. In such cases of astigmatism the meridians of greater curvatures are leaning in the same direction, but not parallel, and the leaning is toward the nose and greater in the hyperphoric eye. Correct this astigmatism and the hyperphoria vanishes like mist before the morning sun.

There was a very interesting case here yesterday in a man with less than 1 degree of right hyperphoria, whose eyes are subjected to 2 degrees of vertical prismatic effect. He gets more relief from that than from weaker prisms. This case was investigated first by an eminent ophthalmologist, who found no hyperphoria at all and who was later induced to operate on the internal rectus of the left eye for esophoria. (If he had divided the lower fibers of the internal rectus of the right eye I believe he would have corrected the trouble.) On examining this case yesterday I found he had a well-marked plus cyclophoria; and I found this to explain the relief he gets from those prisms. I tried first a 1-degree prism before each eye with no comfort; and then a 1½-degree prism, base down, before right eye and a ½-degree base up before the left; that combination gives him the most relief. He thus allows the eye to turn up and is getting relief, not because of any hyperphoria primarily, but because the prism thus placed enables the superior rectus of the right eye to torsion the eye in and help the weak superior oblique, while the prism before left eye causes it to slightly torsion out, but leaving the vertical meridians parallel. I will close with this remark, that I never operate on a case of hyperphoria without knowing where the cause resides and the conditions that complicate it, and never on a case of less than 2 degrees. If a man operates on the superior muscle for hyperphoria and divides more fibers on the outer side than the inner he will lead to more suffering than if he had done nothing. As a rule it is better to divide all the internal fibers of a superior muscle than even the central fibers, and if the outer fibers are divided the patient will be worse in the end than if he had never been touched.

DR. C. F. CLARK, Columbus—I can not help feeling that most of us are mystified by this muscle question. I have enjoyed Dr. Reber's paper very much and feel that it is deserving of credit, but that we need some foundation principles to base our study upon.

DR. JOHN T. CARPENTER, Philadelphia—I think Dr. Reber deserves credit for bringing forward, at this time, a paper dealing with the treatment of defects of the ocular muscles. I have been impressed by the manner in which any reference to this subject is met by many ophthalmologists. There is complete contempt for the question of the surgical treatment of muscular abnormalities. As an instance of extreme opposition I was lately told by a man well known in our special line, when speaking of a patient whom I had cured by tenotomy of the superior rectus, that I ought to have been prosecuted for doing the tenotomy. Dr. Reber has handled this subject in a calm, judicious manner, and we should all try to help clear up this "dark region" in ophthalmic science.

DR. WENDELL REBER, Philadelphia—I am gratified at this expression of opinion. Dr. Stevenson's modification of the cover test is one I have employed for a long time, and I am not sure that he and I have not talked about it. I think the Maddox rod test the most trustworthy yet offered. We know very little about the physiology of the ocular muscles. When we reflect that there are six pairs of muscles, that no one is concerned alone in any movement of the eyes; and that according to Volkmann there are something near 200 possible combinations of these movements, we will perhaps realize how empirical our present knowledge is.

As to Dr. Thompson's question whether I cut all the muscle, I would say that I do not do partial tenotomies, but complete ones. I shall do partial ones only when clinical evidence of a convincing nature has been produced.

DR. SAVAGE—Do I understand that you do a complete tenotomy on the superior rectus for 2 degrees of hyperphoria

DR. REBER—Yes.

DR. WILLIAM THOMSON—Have you had many occasions requiring a restricting stitch?

DR. REBER—I have had overcorrection in one case and I preferred to trust the re-establishment of normal conditions to the patient's brain, believing that the brain can take better care of such temporary apparent overcorrections than the surgeon can.

OCULAR COMPLICATIONS OF INJURIES TO THE HEAD.*

JOHN T. CARPENTER, M.D.

PHILADELPHIA.

The clinical fact that blindness may follow blows on the head is by no means new, but until Berlin, in 1879, cleared up the pathology of these cases, their etiology was clouded in vague conjecture. Beer attributed the amaurosis following head injuries to the reflex influence of the supraorbital nerve. The result of anatomic studies, however, by Berlin, Leber, and Von Hölder, proved that direct damage to the optic nerve or its sheath in the foramen opticum by fracture of the orbital wall frequently occurred. Von Hölder, in his cases studied postmortem, found fracture of the orbital vault in 90 per cent., while the optic canal was implicated in about 60 per cent. There were hemorrhages into the nerve sheath in about 48 per cent. of the 88 cases. The line of fracture in some instances passed through both foramina. In Treves' "System of Surgery," illustrations show the line of fracture in two cases passing through both optic foramina, so that the blindness may be bilateral; indeed, it may even be on the opposite side to the injury by the contre coup.

Following Berlin's communication at the German Congress in 1879, there appeared reports of optic neuritis, of atrophy, and of hemianopsia resulting from blows or falls on the head. Most of the reported cases were of monocular blindness, caused by such blows or falls, the subsequent optic atrophy showing that the nerve had been severed or compressed, producing descending degeneration, with the ophthalmoscopic signs of simple atrophy, in about three weeks. Ocular complications have been recognized by surgical authors as of important corroborative value in fracture of the base of the skull; and conjunctival ecchymosis, appearing some hours or days after the injury is one of the classic signs of these fractures. Emphysema of the orbit or lids proved the existence of a fracture of the orbital walls communicating with the air cells in the neighborhood of the orbit. In 1882, Von Bergmann called attention to the fact that rapidly increasing hemorrhage into the cranial cavity produced the same disturbance in intracranial pressure that was found in brain tumors; and thus a "choked disc" might accompany cerebral hemorrhage, as well as tumor of the brain. Optic neuritis might, however, be due to direct damage to the foramen by fracture or laceration, and not to increase of the intracranial pressure. The grave and even fatal nature of the injury may completely overshadow the ocular symptoms, but interesting instances are recorded in which, with almost no general disturbance, complete and permanent blindness ensued. Knies relates the history of a railroad official who, while riding in a train, "struck the orbital rim lightly against some obstruction. The patient was not unconscious for a moment, but from that time on he was blind on the side of the injury."

---

*Presented to the Section on Ophthalmology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Head injuries may be perforating or non-perforating in character. The eye or its appendages may be directly injured by a bullet, a sharp implement, or a fall on a pointed stick; but in these instances the injury is an obvious one, and the case presents interest only in the light of its clinical symptoms. The eye-ball may be ruptured and destroyed or the optic nerve may be severed or torn, and the extraocular muscles may be paralyzed by damage done to their nerve supply or to the muscles themselves. Of these cases I shall not treat further. So, also, in non-perforating injury, there may be ocular complications, such as intraocular hemorrhage, dislocation of the lens—at times producing secondary glaucoma—traumatic mydriasis, or even rupture of the iris. The deeper ocular tunics may be damaged, or there may be enophthalmos or exophthalmos with pulsation. These various conditions, while presenting interesting features, can not be included in a short paper, but must be studied separately from their clinical point of view. I shall confine myself to those obscure ocular lesions following head injuries, in which the optic nerve or some of the other cranial nerves are affected.

Blows or falls on the head produce ocular symptoms by extension of fracture into the orbit; by contre coup; by hemorrhage into the nerves or their sheaths; by meningitis at the base of the brain; by localized injury to the optic chiasm or to the neighborhood of the visual centers, producing hemianopsia. This subject is interesting from its medicolegal standpoint, and in the first case reported in this paper heavy damages were secured by establishing the relation between the injury to the head and neuritis and partial atrophy of the optic nerve which resulted. Gowers treats the subject of injuries to the head under four divisions:

1. Impairment or loss of sight without ophthalmoscopic signs. In some of these cases he thinks the mischief is direct concussion of the retina.
2. Optic neuritis following at an interval of from a few days to several weeks. In these cases he thinks that the neuritis is due to meningitis; or less commonly to traumatic inflammatory softening of the brain.
3. Simple atrophy. In such cases sight often fails, while the atrophy develops ophthalmoscopic signs later.
4. Gradual failure of sight, with slight and stationary papillitis, probably due to chronic interstitial neuritis in the nerve trunk. The first case which I shall report is best included in the fourth class, as the nature of the lesion, while necessarily somewhat uncertain, is best explained as a partial degeneration of the optic nerve following an interstitial neuritis of the nerve trunk.

CASE 1.—Philip L., aged 36, consulted me Jan. 22, 1896, because of rapidly failing vision. He gave the following history: Five weeks before seeking advice, while driving a team of horses, the pole of the carriage was struck by a rapidly moving trolley car. He was thrown to the ground, striking the right side of his head. For a few minutes he was dazed, but considered himself little hurt and was able to walk home with one of the horses, which survived the wreck. He worked as usual for four days, but was then compelled to give up because of headache, vomiting and pain in his back. Ten days after the accident he first noticed dimness of vision. There seemed to be a "mist in front of objects," and he was unable to read his instructions or to distinguish the numbers over the front doors. Two weeks after the accident, when his vision was so much reduced that he "could hardly get around," his eyes were examined by a very competent ophthalmic surgeon, who found very poor vision, dilated pupils, and negative ophthalmoscopic appearances. He thinks that his vision began to improve about four weeks after the injury, and now—five weeks later—he can read large letters by looking at them sidewise.

On examination I noted: Pupils dilated and fixed; amaurotic expression; moves his eyes rapidly to and fro, which, he affirms, enables him to distinguish objects more clearly. Right vision is 4/60; left vision, 1/60. He is unable to read any type. Field shows absolute central scotoma in each eye, about 25° × 20° in extent. Peripheral fields are normal. The ophthalmoscopic examination showed almost emmetropic refractive condition, low-grade optic neuritis with one or two small fresh hemorrhages on and near the nerve-head. The retinal veins are swollen and tortuous; the nerve-head is slightly swollen, of dirty, reddish-gray color, especially dense on nasal edge. The temporal edge is clearer, and the outer fourth of disc is pallid looking. Both direct and indirect methods show complete veiling of the upper, lower, and inner nerve edges, and the swollen portion is seen to be composed of striated nerve fibers, with small red points like minute hemorrhages mingled with gray inflammatory exudate.

There was no evidence of syphilis. He was married and had healthy children. He had never suffered from any illness whatever; his habits were most temperate, and he was apparently in vigorous health. Urine was 1018; negative tests for albumin and sugar; no sediment. The diagnosis of descending neuritis from localized traumatic meningitis at the base of brain, involving the optic nerves, was made. The treatment was heroic in view of the serious nature of the lesion. Mercury was pushed by inunction and iodid of mercury in pill form until marked symptoms of ptyalism developed. In about three weeks he was placed on ascending doses of potassium iodid until his daily dose reached 120 grs.; his vision improved but little, and the nerves passed slowly into an atrophic state. Three months afterward, his vision and scotoma remaining about the same, he was given strychnin in increasing doses and pilocarpin ⅛ gr. hypodermically, three times a week.

Slight improvement resulted, but the final vision gained was 4/60 for each eye, in December, 1896. When last seen, January, 1900, his vision was 10/200, and the ophthalmoscope showed apparently complete atrophy of the discs. The peripheral field remains excellent; and owing to this fact he is able to go around without difficulty. There is still an absolute central scotoma surrounding the fixation point.

We have here a comparatively slight injury to the head, after which the patient, though dazed, was not unconscious. He was able to walk to his home and reported for work the next day, being inconvenienced only by a general bruising of his body. For a week after the injury he suffered severely from headache and pains in the back. On about the tenth day he first complained of visual symptoms. Both pupils were widely dilated and fixed, and the optic nerves, examined by a confrère, presented nothing abnormal. In from three to four weeks after the injury, a low-grade optic neuritis manifested itself. Central vision was greatly reduced and an absolute central scotoma was then mapped out, which has remained permanent. The eyes passed into a condition of partial atrophy and his final central vision nearly five years after the accident is 10/200 with absolute central scotoma and a normal peripheral field.

In the trial which followed, the medical testimony for the defense included an attempt to attribute the neuritis to some general systemic cause, but as there was an entire absence of any constitutional disease, the patient enjoying vigorous health both before and since the accident, and in the light of previously reported cases, similar injury was shown to have produced like results, damages were justly given in favor of my patient, for partial loss of eyesight. Toxic neuritis was excluded after most careful investigation.

We are concerned here with the difficulty of explaining the exact nature of the damage evidently inflicted on the optic nerve at some distance behind the eye-ball. There was probably an axial neuritis, producing almost complete central blindness, with intact peripheral field. This is not the usual picture of fracture of the orbit passing through the optic foramen. The injury was bilateral and the visual fields singularly affected in the central portion only.

Our present anatomic knowledge of the course of the macular fibers behind the eye-ball places them in a position apparently inaccessible to injury, without affecting the fibers supplying the periphery of the retina; *but after a careful study of the clinical facts,* I am inclined to believe the bilateral injury affected the axial fibers in each optic nerve, as a result of traumatic shock. Gowers says, in his work on "Medical Ophthalmoscopy": "Blows on the head commonly produce atrophy by direct injury to the nerve, but it is probable that they occasionally cause, by the effect of the shock, a gradual degeneration." He lays stress on the early loss of vision in these cases, with later ophthalmoscopic findings. He states that in some cases an injury to the head may be followed by a gradual failure of sight, with slight, stationary papillitis, probably a chronic interstitial neuritis in the nerve trunk.

There were no marked symptoms in my patient's case of traumatic meningitis, although he suffered from severe headache, some vomiting, and backache. In the discussion of Callan's article, "Transactions of American Ophthalmological Society," 1891, Dr. Myles Standish reported two cases of great medicolegal interest. Two individuals claimed damages for blindness said to have been caused by a blow on the head. Pupils reacted to light, and there was no ophthalmoscopic change, so that he reported malingering; but to his chagrin, both cases showed complete monocular atrophy and absolute blindness when examined three months later. Dr. Lippincott, at the recent meeting of the American Ophthalmological Society, related a similar experience.

Case 2.—John H. P., aged 10, was seen in consultation *with Dr. F. A. Packard, April 9, 1894.* The following history was obtained: Four days ago, without warning, he awoke with severe frontal pain and fever. Temperature was 101; pulse, 100. There was slight stupor, but the patient could be easily aroused. Light caused irritation and complaint, and yesterday he first noticed diplopia. Dr. Packard reported that there had been no marked strabismus. Today there is intense frontal headache and some occipital pain; slight retraction of the head; and on sitting up, he complains of pain in the back. The left ear shows a bluish discoloration from a blow on the left side of the head, received five days before by being pushed against a lamp-post by a playmate. I noted the following ocular conditions: Marked convergent strabismus, homonymous diplopia, except when candle was held directly in front. Each eye can be moved outward, so that the cornea touches the outer canthus; but it can not be held there, as the eye, after a series of jerks, is carried inward. There is evidently paresis of the externi, or spasm of the interni. Left outward rotation seems to be more defective and accomplished with greater difficulty than on the right side. Pupils are "large medium," but responsive, slightly less so on the left side. Some pain is felt in the left eye when it is pushed back into the orbit.

The ophthalmoscope shows in the left eye marked optic neuritis. Nerve edges swollen and obscured by retinal striation; veins swollen and tortuous; arteries not reduced in size, but the vessels are partly hidden near the disc by retinal edema. The summit of swollen disc is seen with + 5 D.; macular pigment, with + 2½ D. Right eye shows media clear; hypermetropia, 2 D.; nerve head not swollen; no retinal haze. The fundus presents usual changes of hypermetropia. On the following day, convergent strabismus was more marked. He closed one eye, usually the right, to get rid of the annoying diplopia. Temperature was 99; patient bright and cheerful. Vision roughly tested with small type, seems to be unaffected. The treatment instituted was calomel, gr. 1/6 every hour. Mercurial inunctions night and morning.

April 13: Now fixes constantly with the right eye, closing the left. Left-sided ptosis appeared to-day. Ophthalmoscope shows no alterations in fundus since last examined.

April 14: Mercurial inunctions stopped, patient being ptyalized. Ophthalmoscope shows less marked venous stasis, but no nerve edges are yet made out. Atropin is ordered for each eye. Four days later there was continued improvement in both the general and local symptoms. Convergent strabismus was less marked. Summit of nerve +5 D., and its edges hidden to both direct and indirect methods. One week later, and almost three weeks after the accident, the ptosis had almost disappeared; there was no strabismus. Diplopia was noticed only in the extreme outer field.

April 22: Ophthalmoscope now shows temporal edge beginning to appear. Disc, dull-red, as seen through a fog, and slightly swollen. One week later there were no signs of ocular paralysis and the nerve-head had almost regained its normal condition. By the middle of May, atropin was stopped, glasses correcting his refractive error having previously been ordered. The patient has had no further symptoms of the ocular trouble. His vision and eye grounds are normal.

The interesting points in the case are the irritative symptoms, namely, spasm of convergence and photophobia, due to traumatic meningitis of the anterior portion of the skull, followed by paresis of the left external rectus and levator palpebræ superioris, with left optic neuritis. The association of paralysis of a branch of the third, with paralysis of the sixth nerves, and optic neuritis on the same side, make it possible to locate the intracranial lesion at or near the sphenoidal fissure.

Cases of traumatic paralysis of the ocular muscles are by no means rare, the external rectus suffering most frequently; but the association of no less than three of the cranial nerves, as occurred in this case, seemed, in my opinion, to justify this report.

DISCUSSION.

Dr. H. F. Hansell, Philadelphia—I had the opportunity of seeing the first case reported by Dr. Carpenter and the pain of having to testify in court as to the nature of the injury. I thought at the time that it was a fracture of the sphenoid bone, producing an injury to the meninges directly over the optic nerve, and that this meningitis produced later a central degeneration of the optic nerve. I was led to that conclusion by an experience I had in a case of purulent disease of the accessory sinuses of the eye in which the scotoma was just as pronounced and incurable as it was in this case. The scotomas were exactly alike in both eyes, and that seems to exclude direct injury to the optic foramen, and to the nerves passing through it. In that case the sphenoidal sinuses were filled with pus. The patient lost his sight over night, probably by the acute and rapid extension of inflammation to the membranes lying on the body of the sphenoid bone.

In connection with this case I would like to report a case studied very carefully with Dr. Spiller. R. T., aged 30, railroad employee, brought to the Polyclinic Hospital on July 7, 1898, while intoxicated received a punctured transverse wound in the lower lid of the right eye from the thrust of an umbrella ferrule. When he was brought to the hospital he was unconscious.

his muscles were relaxed, the skin was blanched, the extremities were cold, and the heart's action was weak—results of the injury and partly, perhaps, of alcohol. A few minutes after his reception he could be roused sufficiently to answer questions. He was put to bed and to quiet his extreme restlessness and the complaints of pain, morphia and bromids were given. The ragged linear wound in the lids was just above the margin of the floor of the right orbit. No fracture of the bony floor or walls could be detected. The left side of the face was paralyzed, Ptosis was complete on the right side, the right eye was slightly prominent and immovable by any voluntary effort. He had absolute ophthalmoplegia of all the external and internal muscles of the right side. The pupil was moderately dilated and irresponsive to the stimulus of light or convergence. Accommodation was abolished. There was indistinctness of outline of the margin of the disc; otherwise the fundus had undergone no change. Subsequent examinations made while the patient was in the hospital showed no improvement in the ocular conditions excepting a subsidence of the edema. About 6 months after the accident, the muscles of the exterior and interior of the eye had regained to a great extent their normal power. Some restriction of movement in all directions, a partially dilated and sluggish iris, and inability to read fine print were still evident. Diplopia, the eye symptom that was prominent from the first, continued in all parts of the binocular field, although the separation of the false and true images was less marked. Shortly after the accident the left side of the face and the left arm were noticed to be paralyzed and the left leg paretic. Paroxysms of severe pain in the distribution of the ophthalmic branch of the right 5th nerve occurred several times daily during the first two weeks, and perhaps a little longer. A consideration of the history and symptoms of this case in which we have paralysis of the 3d, 4th, the ophthalmic division of the 5th and 6th nerve, with a transitory perversion of the function of the 2d, leads inevitably to the conclusion that the umbrella tip penetrated the right orbit and injured these nerves at the point where they lie close together, namely, the sphenoidal fissure. The escape of the optic nerve from injury shows that its site, above and to the inner side of the sphenoidal opening, was not invaded. We can hardly imagine a lesion that would produce complete paralysis of all the orbital nerves except the optic, unless it were situated at the sphenoidal fissure, where these nerves are close together. The exophthalmos, noticed at first, was probably produced by the complete paralysis of all the external ocular muscles and the loss thereby of the muscular tonicity. After the muscular power was in a measure regained the exophthalmos entirely disappeared.

DR. W. L. DAYTON, Lincoln Neb.—In connection with Dr. Carpenter's paper, I wish to mention two cases that came under my observation in the latter part of 1898. One was a case of a railroad engineer who, in getting on his cab with the long nozzle oil-can in his hand, slipped and fell upon the curved extremity of the nozzle so that it penetrated the orbit and evidently injured the optic nerve directly. At least I thought this was the case on account of the condition of the circulation that existed for months afterward. I saw him within two hours after the accident and there were negative ophthalmoscopic signs. He was perfectly blind, but there was no hemorrhage apparent from the cut, which I stitched together, and it healed kindly. Although we kept him under treatment for prudential reasons for some time, he had, when discharged, a divergent strabismus and the ophthalmoscope showed a progressive atrophy. The vascular condition was remarkable, the veins being full, arteries large and there was not a great amount of tortuosity.

Five or six weeks after that a little boy 7 years old, while playing Indian, had the pointed extremity of a wooden sword jammed into his eye in the same position as in the former case, namely, the inferior sulcus, without injuring the eyeball. There was almost immediate total blindness without ophthalmoscopic signs, and now there is a divergent squint.

DR. H. W. SEABROOK, New York City—Dr. Dayton's remark about the hopelessness of the prognosis in these cases leads me to report a case of injury to the eyeball occurring in January last. Two men were fencing in the theater when one received an injury by the other's foil penetrating the orbit; the tissues at the inner side of the eyeball were torn through, including the internal rectus; he had complete paralysis of all the muscles supplied by the 3d nerve, and though there was no trouble with the retinal circulation as yet, there was total blindness. On the fifth day the man began to see light and at the end of ten days had vision of 20/200, with the upper part of the field cut off. There was some divergence left when I saw him three or four weeks after the injury. It would seem as if the unbroken end of the foil had carried the eyeball upward and outward, pulling upon the optic nerve at the foramen and bruising or lacerating its lower and inner fibers only.

THE SILVER-INJECTION TREATMENT OF PULMONARY CONSUMPTION.*

THOMAS J. MAYS, A.M., M.D.
PHILADELPHIA.

That the nervous system is generally, and the pneumogastric nerves are especially, implicated in pulmonary consumption, and that any therapeutic agent which affects this disease favorably and permanently either appeals directly or indirectly to the pulmonary organs through the nervous system, have been regarded by me as cardinal truths for more than a dozen years. This is clearly confirmed on its pathologic side. For, it may be said, that any influence or agent that has the power of undermining the integrity of the nervous system also has the power of generating pulmonary consumption, or some other form of pulmonary disease. Herein lies the reason why the insane, the idiotic, the epileptic, the hysteric, the asthmatic, the neurotic; why those who are subject to great grief, worry, mental overwork, disappointment, etc., and why those whose nervous systems suffer from the chronic intoxication of alcohol, syphilis, lead, mercury, etc., are much more prone to die of phthisis than others differently situated. On the other hand, when we review the therapeutic history of phthisis it will be found that those agents which have the greatest staying power against the ravages of this disease act almost exclusively by the support which they give to the nervous system. This is true of strychnin, the hypophosphites, atropin, cod-liver oil, cayenne pepper, arsenic, electricity, and other drugs and agents that are constantly employed in the treatment of this disease.

In keeping with this theory I made an effort some years ago to reach the lung condition of this disease through the pneumogastric nerves by massaging, kneading and compressing them through the overlying textures in the neck. This benefited the cough and expectoration and improved the patients in other ways, but it became evident after a while that the influence of this measure did not possess sufficient stimulating power to make it of decided value. I then had in mind to stimulate these nerves by stretching them according to the methods of M. Jaboulay,[1] who had obtained good results from this operation in severe cough associated with exophthalmic goiter, when it appeared to me that the subcutaneous introduction of some well-known conservative irritant, like nitrate of silver, immediately over the course of the nerves in the neck might furnish the stimulus necessary to modify the morbid condition of the lungs. That counter-irritation over the trunk of a nerve serves to enhance the tone and resistance of the neuritis to some general systemic cause, but as there was an entire absence of any constitutional disease, the patient enjoying vigorous health both before and since the accident, and in the light of previously reported cases, similar injury was shown to have produced like results, damages were justly given in favor of my patient, for partial loss of eyesight. Toxic neuritis was excluded after most careful investigation.

---

* Presented in a Symposium on Tuberculosis, to the Section on Practice of Medicine, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

[1] Stretching the Pneumogastric Nerve, M. Jaboulay, N. Y. Medical Journal, May 7, 1898, abstracted from Lyon Medical, April 17, 1898.

We are concerned here with the difficulty of explaining the exact nature of the damage evidently inflicted on the optic nerve at some distance behind the eye-ball. There was probably an axial neuritis, producing almost complete central blindness, with intact peripheral field. This is not the usual picture of fracture of the orbit passing through the optic foramen. The injury was bilateral and the visual fields singularly affected in the central portion only.

Our present anatomic knowledge of the course of the macular fibers behind the eye-ball places them in a position apparently inaccessible to injury, without affecting the fibers supplying the periphery of the retina; but after a careful study of the clinical facts, I am inclined to believe the bilateral injury affected the axial fibers in each optic nerve, as a result of traumatic shock. Gowers says, in his work on "Medical Ophthalmoscopy": "Blows on the head commonly produce atrophy by direct injury to the nerve, but it is probable that they occasionally cause, by the effect of the shock, a gradual degeneration." He lays stress on the early loss of vision in these cases, with later ophthalmoscopic findings. He states that in some cases an injury to the head may be followed by a gradual failure of sight, with slight, stationary papillitis, probably a chronic interstitial neuritis in the nerve trunk.

There were no marked symptoms in my patient's case of traumatic meningitis, although he suffered from severe headache, some vomiting, and backache. In the discussion of Callan's article, "Transactions of American Ophthalmological Society," 1891, Dr. Myles Standish reported two cases of great medicolegal interest. Two individuals claimed damages for blindness said to have been caused by a blow on the head. Pupils reacted to light, and there was no ophthalmoscopic change, so that he reported malingering; but to his chagrin, both cases showed complete monocular atrophy and absolute blindness when examined three months later. Dr. Lippincott, at the recent meeting of the American Ophthalmological Society, related a similar experience.

Case 2.—John H. P., aged 10, was seen in consultation with Dr. F. A. Packard, April 9, 1894. The following history was obtained: Four days ago, without warning, he awoke with severe frontal pain and fever. Temperature was 101; pulse, 100. There was slight stupor, but the patient could be easily aroused. Light caused irritation and complaint, and yesterday he first noticed diplopia. Dr. Packard reported that there had been no marked strabismus. Today there is intense frontal headache and some occipital pain; slight retraction of the head; and on sitting up, he complains of pain in the back. The left ear shows a bluish discoloration from a blow on the left side of the head, received five days before by being pushed against a lamp-post by a playmate. I noted the following ocular conditions: Marked convergent strabismus, homonymous diplopia, except when candle was held directly in front. Each eye can be moved outward, so that the cornea touches the outer canthus; but it can not be held there, as the eye, after a series of jerks, is carried inward. There is evidently paresis of the externi, or spasm of the interni. Left outward rotation seems to be more defective and accomplished with greater difficulty than on the right side. Pupils are "large medium," but responsive, slightly less so on the left side. Some pain is felt in the left eye when it is pushed back into the orbit.

The ophthalmoscope shows in the left eye marked optic neuritis. Nerve edges swollen and obscured by retinal striation; veins swollen and tortuous; arteries not reduced in size, but the vessels are partly hidden near the disc by retinal edema. The summit of swollen disc is seen with + 5 D.; macular pigment, with + 2½ D. Right eye shows media clear; hypermetropia, 2 D.; nerve head not swollen; no retinal haze. The fundus presents usual changes of hypermetropia. On the following day, convergent strabismus was more marked. He closed one eye, usually the right, to get rid of the annoying diplopia. Temperature was 99; patient bright and cheerful. Vision roughly tested with small type, seems to be unaffected. The treatment instituted was calomel, gr. 1/6 every hour. Mercurial inunctions night and morning.

April 13: Now fixes constantly with the right eye, closing the left. Left-sided ptosis appeared to-day. Ophthalmoscope shows no alterations in fundus since last examined.

April 14: Mercurial inunctions stopped, patient being ptyalized. Ophthalmoscope shows less marked venous stasis, but no nerve edges are yet made out. Atropin is ordered for each eye. Four days later there was continued improvement in both the general and local symptoms. Convergent strabismus was less marked. Summit of nerve +5 D., and its edges hidden to both direct and indirect methods. One week later, and almost three weeks after the accident, the ptosis had almost disappeared; there was no strabismus. Diplopia was noticed only in the extreme outer field.

April 22: Ophthalmoscope now shows temporal edge beginning to appear. Disc, dull-red, as seen through a fog, and slightly swollen. One week later there were no signs of ocular paralysis and the nerve-head had almost regained its normal condition. By the middle of May, atropin was stopped, glasses correcting his refractive error having previously been ordered. The patient has had no further symptoms of the ocular trouble. His vision and eye grounds are normal.

The interesting points in the case are the irritative symptoms, namely, spasm of convergence and photophobia, due to traumatic meningitis of the anterior portion of the skull, followed by paresis of the left external rectus and levator palpebræ superioris, with left optic neuritis. The association of paralysis of a branch of the third, with paralysis of the sixth nerves, and optic neuritis on the same side, make it possible to locate the intracranial lesion at or near the sphenoidal fissure.

Cases of traumatic paralysis of the ocular muscles are by no means rare, the external rectus suffering most frequently; but the association of no less than three of the cranial nerves, as occurred in this case, seemed, in my opinion, to justify this report.

DISCUSSION.

Dr. H. F. Hansell, Philadelphia—I had the opportunity of seeing the first case reported by Dr. Carpenter and the pain of having to testify in court as to the nature of the injury. I thought at the time that it was a fracture of the sphenoid bone, producing an injury to the meninges directly over the optic nerve, and that this meningitis produced later a central degeneration of the optic nerve. I was led to that conclusion by an experience I had in a case of purulent disease of the accessory sinuses of the eye in which the scotoma was just as pronounced and incurable as it was in this case. The scotomas were exactly alike in both eyes, and that seems to exclude direct injury to the optic foramen, and to the nerves passing through it. In that case the sphenoidal sinuses were filled with pus. The patient lost his sight over night, probably by the acute and rapid extension of inflammation to the membranes lying on the body of the sphenoid bone.

In connection with this case I would like to report a case studied very carefully with Dr. Spiller. R. T., aged 30, railroad employee, brought to the Polyclinic Hospital on July 7, 1898, while intoxicated received a punctured transverse wound in the lower lid of the right eye from the thrust of an umbrella ferrule. When he was brought to the hospital he was unconscious.

his muscles were relaxed, the skin was blanched, the extremities were cold, and the heart's action was weak—results of the injury and partly, perhaps, of alcohol. A few minutes after his reception he could be roused sufficiently to answer questions. He was put to bed and to quiet his extreme restlessness and complaints of pain, morphia and bromids were given. The ragged linear wound in the lids was just above the margin of the floor of the right orbit. No fracture of the bony floor or walls could be detected. The left side of the face was paralyzed. Ptosis was complete on the right side, the right eye was slightly prominent and immovable by any voluntary effort. He had absolute ophthalmoplegia of all the external and internal muscles of the right side. The pupil was moderately dilated and irresponsive to the stimulus of light or convergence. Accommodation was abolished. There was indistinctness of outline of the margin of the disc; otherwise the fundus had undergone no change. Subsequent examinations made while the patient was in the hospital showed no improvement in the ocular conditions excepting a subsidence of the edema. About 6 months after the accident, the muscles of the exterior and interior of the eye had regained to a great extent their normal power. Some restriction of movement in all directions, a partially dilated and sluggish iris, and inability to read fine print were still evident. Diplopia, the eye symptom that was prominent from the first, continued in all parts of the binocular field, although the separation of the false and true images was less marked. Shortly after the accident the left side of the face and the left arm were noticed to be paralyzed and the left leg paretic. Paroxysms of severe pain in the distribution of the ophthalmic branch of the right 5th nerve occurred several times daily during the first two weeks, and perhaps a little longer. A consideration of the history and symptoms of this case in which we have paralysis of the 3d, 4th, the ophthalmic division of the 5th and 6th nerve, with a transitory perversion of the function of the 2d, leads inevitably to the conclusion that the umbrella tip penetrated the right orbit and injured these nerves at the point where they lie close together, namely, the sphenoidal fissure. The escape of the optic nerve from injury shows that its site, above and to the inner side of the sphenoidal opening, was not invaded. We can hardly imagine a lesion that would produce complete paralysis of all the orbital nerves except the optic, unless it were situated at the sphenoidal fissure, where these nerves are close together. The exophthalmos, noticed at first, was probably produced by the complete paralysis of all the external ocular muscles and the loss thereby of the muscular tonicity. After the muscular power was in a measure regained the exophthalmos entirely disappeared.

Dr. W. L. Dayton, Lincoln Neb.—In connection with Dr. Carpenter's paper, I wish to mention two cases that came under my observation in the latter part of 1898. One was a case of a railroad engineer who, in getting on his cab with the long nozzle oil-can in his hand, slipped and fell upon the curved extremity of the nozzle so that it penetrated the orbit and evidently injured the optic nerve directly. At least I thought this was the case on account of the condition of the circulation that existed for months afterward. I saw him within two hours after the accident and there were negative ophthalmoscopic signs. He was perfectly blind, but there was no hemorrhage apparent from the cut, which I stitched together, and it healed kindly. Although we kept him under treatment for prudential reasons for some time, he had, when discharged, a divergent strabismus and the ophthalmoscope showed a progressive atrophy. The vascular condition was remarkable, the veins being full, arteries large and there was not a great amount of tortuosity.

Five or six weeks after that a little boy 7 years old, while playing Indian, had the pointed extremity of a wooden sword jammed into his eye in the same position as in the former case, namely, the inferior sulcus, without injuring the eyeball. There was almost immediate total blindness without ophthalmoscopic signs, and now there is a divergent squint.

Dr. H. W. Seabrook, New York City—Dr. Dayton's remark about the hopelessness of the prognosis in these cases leads me to report a case of injury to the eyeball occurring in January last. Two men were fencing in the theater when one received an injury by the other's foil penetrating the orbit; the tissues at the inner side of the eyeball were torn through, including the internal rectus; he had complete paralysis of all the muscles supplied by the 3d nerve, and though there was no trouble with the retinal circulation as yet, there was total blindness. On the fifth day the man began to see light and at the end of ten days had vision of 20/200, with the upper part of the field cut off. There was some divergence left when I saw him three or four weeks after the injury. It would seem as if the unbroken end of the foil had carried the eyeball upward and outward, pulling upon the optic nerve at the foramen and bruising or lacerating its lower and inner fibers only.

THE SILVER-INJECTION TREATMENT OF PULMONARY CONSUMPTION.*

THOMAS J. MAYS, A.M., M.D.
PHILADELPHIA.

That the nervous system is generally, and the pneumogastric nerves are especially, implicated in pulmonary consumption, and that any therapeutic agent which affects this disease favorably and permanently either appeals directly or indirectly to the pulmonary organs through the nervous system, have been regarded by me as cardinal truths for more than a dozen years. This is clearly confirmed on its pathologic side. For, it may be said, that any influence or agent that has the power of undermining the integrity of the nervous system also has the power of generating pulmonary consumption, or some other form of pulmonary disease. Herein lies the reason why the insane, the idiotic, the epileptic, the hysteric, the asthmatic, the neurotic; why those who are subject to great grief, worry, mental overwork, disappointment, etc., and why those whose nervous systems suffer from the chronic intoxication of alcohol, syphilis, lead, mercury, etc., are much more prone to die of phthisis than others differently situated. On the other hand, when we review the therapeutic history of phthisis it will be found that those agents which have the greatest staying power against the ravages of this disease act almost exclusively by the support which they give to the nervous system. This is true of strychnin, the hypophosphites, atropin, cod-liver oil, cayenne pepper, arsenic, electricity, and other drugs and agents that are constantly employed in the treatment of this disease.

In keeping with this theory I made an effort some years ago to reach the lung condition of this disease through the pneumogastric nerves by massaging, kneading and compressing them through the overlying textures in the neck. This benefited the cough and expectoration and improved the patients in other ways, but it became evident after a while that the influence of this measure did not possess sufficient stimulating power to make it of decided value. I then had in mind to stimulate these nerves by stretching them according to the methods of M. Jaboulay,[1] who had obtained good results from this operation in severe cough associated with exophthalmic goiter, when it appeared to me that the subcutaneous introduction of some well-known conservative irritant, like nitrate of silver, immediately over the course of the nerves in the neck might furnish the stimulus necessary to modify the morbid condition of the lungs. That counter-irritation over the trunk of a nerve serves to enhance the tone and resistance of the region to which the latter is distributed is a well-recognized therapeutic principle in other fields of disease. Thus, the influence of acupuncture, and of stretching the sciatic nerve in sciatica, the application of a blister over the root of a spinal nerve in herpes-zoster, or an intercostal neuralgia, are well-known examples of this class of remedies.

---

* Presented in a Symposium on Tuberculosis, to the Section on Practice of Medicine, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

[1] Stretching the Pneumogastric Nerve, M. Jaboulay, N. Y. Medical Journal, May 7, 1898, abstracted from Lyon Medical, April 17, 1898.

Nitrate of silver was selected for this purpose, not because it was believed to be the only agent that could furnish the requisite degree of stimulation, but because more was known concerning its hypodermic use and action than of some others that might have been employed. In searching for the proper dose to be injected it was found, after many trials, that 5 minims of a 2.5 per cent. solution of this agent answered the purpose best in the greatest number of cases, preceded by a cocain solution of the same strength and dose—the latter being used to abate the pain which would be produced by the former when given alone. The point of introduction is immediately over, or slightly behind, the pulsating carotid artery in the neck, between the angle of the lower jaw and the clavicle. In order to avoid puncturing the underlying blood-vessels it was important to lift the skin between the thumb and the forefinger of the left hand and to push the needle just through the skin. To introduce these agents the following is a very practical plan: Inject the cocain solution, detach the syringe from the needle, and let the latter remain in the puncture. Wash out the syringe with water, draw the silver solution into the syringe, attach the latter to the needle and throw in the required amount. Or a double-barreled syringe containing a single nozzle, to which is attached the needle, may be used. One barrel is filled with the silver and the other with the cocain solution, and the required quantity of each may be injected without detaching the syringe from the needle. The cocain solution should be renewed once a week.

The side of the neck in which the injections are administered is of considerable importance. As a rule, the first injection, and most of its successors, should be given on that side below which the involved lung is located; for it will be found that the vagus on the side of the affected lung is in many phthisical persons more sensitive to pressure than the one on the other side—indicating that the lung and the nerve of that side are simultaneously involved.

The number of injections which are necessary depends on circumstances. The first injection is repeated in a week or ten days, unless there remains too much local irritation. The same interval should elapse between all the successive ones. In urgent cases due to excessive cough I have repeated the injection in three or four days. When both lungs are involved I have in a number of instances given an injection on each side at the same time. There is no special limit to the number of injections that may be given. Twenty-one is the highest number I gave to one patient.

The local effects of the injections show themselves in a nodular, sometimes in a diffuse swelling, and in redness and pain, but in no instance have they become extremely pronounced. Small abscesses do occur occasionally, and in more than two thousand injections, sloughs have occurred twice; but the latter result was probably due to the fact that two successive injections were made in too close proximity to one another. This is to be avoided. So far as my experience extends, the abscesses do no harm, and may do good, inasmuch as they prolong the counterirritant effect.

I have used the silver injections in more than a hundred and fifty cases of pulmonary consumption—extending over a period of twenty-one months—and I now take the liberty of analyzing this therapeutic experience in so far as it has any bearing on the symptoms of this disease. This experience is based partly on that obtained in 40 cases of phthisis, treated with the silver injections since September, 1898,[2] and partly on over a hundred cases treated since in the same way. The results of treatment in the above-named 40 cases after the lapse of about a year and a half is as follows: There were 7 incipient cases. All of these are well and at work, except one. He had a slight relapse during last winter, but responded to the injections a second time, and is well again. Eighteen were in the second or advanced stage. Of these, 5 died, 2 continue invalids and 11 are well and at work. Of the 15 in the third or far-advanced stage, 12 are dead, and 3 alive, 2 of whom are able to be about and do light work. In regard to the high death-rate among the far-advanced class, it may be said that 7 of these were certain to die when the injections were begun—the latter having been given merely for the purpose of ascertaining their influence on such cases. Taking it altogether, therefore, there remains a little over 50 per cent. of the patients of all stages of the disease who are practically well at the end of a year and six months.

The influence of the injections on the symptoms of phthisis may be summed up as follows:

Cough and Expectoration.—Most patients testify that the cough, and especially the expectoration, are increased during the first and sometimes the second day subsequent to the injections, and then gradually diminish. I have seen both cough and expectoration practically relieved by one or two injections in some incipient as well as in some advanced cases. In far-advanced cases their action on these symptoms is less marked, although on the whole it is beneficial. Besides their beneficial influence on the cough and expectoration, the injections also relieve dyspnea and oppression in the chest. This property is well shown in the alleviation which they give to the symptoms of asthma. One consumptive patient, who spent over a year in the Rocky mountains, and who has received a number of injections since his return, stated that "the injections seem to have an effect on respiration similar to that which is produced by a high altitude, inasmuch as I must breathe stronger, deeper and quicker for a day, and sometimes longer, after each insertion." In a paper published in the *Philadelphia Medical Journal* of June 2, 1900, Dr. Richard B. Faulkner, of Pittsburg, stated that in the *New York Medical Record*, of September 25, 1880, he reported a case of a lady, aged 50, a life-long asthmatic, who suffered continuously for 40 days with an attack, and in which morphin, nauseants, antispasmodics, and everything had failed. At the end of this time he applied counter-irritation over the course of the vagus, and relief followed so rapidly and absolutely that ever since he considered this one of the most important of all therapeutic measures. In a number of cases I have seen similar relief follow in the symptoms of asthma from the counterirritation which is caused by the injection of the silver nitrate over the vagus in the cervical region.

Vomiting.—This is one of the most annoying symptoms of phthisis in its lesser stages. It commonly occurs after meals, and is nearly always preceded by cough. The injections measurably control it. A female with incipient infiltration of the right apex, and who is now in her fifth month of pregnancy, was at once relieved of her nausea and vomiting incidental to her pregnant condition after the first injection, which she received over a month ago. This may be a mere coincidence, but it deserves mention since the gastric disorder ceased after the silver was administered.

---

[2] Philadelphia Medical Journal, Feb. 11, 1899.

Appetite.—The power of eating is frequently increased, and sometimes to a remarkable degree. This was, of course, most noticeable in the incipient and advanced, although it also held true in some of the far-advanced cases.

General Strength.—This was greatly benefited in most of the incipient and advanced cases, and also in a number of the far-advanced cases, especially if the injections were combined with regular systematic rest. How to account for the improvement in this respect, which sometimes follows immediately after an injection, is perhaps difficult to explain, but the fact exists and forces itself too often on one's attention to escape notice.

Physical Signs.—In many of the incipient, in some of the advanced, and in a few of the far-advanced cases, there was noticed a pronounced betterment in the physical signs.

Fever.—A reduction of temperature has been observed frequently by the writer. This has also been noticed by others.

Night-Sweats.—In a number of cases night-sweats have ceased.

Weight.—The gain in flesh is principally confined to incipient and advanced cases, but it has also been noted to some extent in far-advanced cases. Indeed, this phenomenon, as it has shown itself in some instances, is really surprising, since it seems barely possible that an almost insignificant quantity of nitrate of silver thrown into the neck once a week should, as I have observed in a number of cases, increase the weight from 4 to 6 pounds a week. Thus, of five patients who have gained most, one gained 5 pounds the first week after the injections were begun, 6 pounds the second, 4 pounds the third, and 3 pounds the fourth week. Another lost 1 pound in two days immediately preceding the first injection, gained 1 pound first week after injection, 4 pounds in second, 3 pounds in third, and 4 pounds in fourth week. Another lost 3 pounds in the five days immediately preceding the first injection, gained 2 pounds in first week after injection, 3 pounds in second, 2 pounds in third, and 4 pounds in fourth week. Another lost 1 pound during week preceding first injection, gained 3 pounds in week after first injection, 4 pounds in second week, and 2 pounds in third week. Another gained 7 pounds in six days after first injection, 3 pounds in second, and 2 pounds in third week. Not all the patients who were benefited by the injections gained in flesh, however, for some lost in weight, or remained at a standstill while improving in every other respect. In regard to other treatment which my patients received, it may be said that some took quinin., strychnin and the hypophosphites, while a number of them in the very early history of the introduction of the treatment, received nothing but peppermint water, or some other placebo. So far as food is concerned, it may be stated that some were nourished well in their homes and in a hospital, yet a number were dispensary visitors, and were naturally subject to the vicissitudes of food-supply that are incidental to the poorer classes of society.

Herewith is given an abstract of the history of 10 cases which were treated with the silver injections.

INCIPIENT CASES.

Case 1.—C. F., colored, age 25, married, was seen first January 5, 1899, when she said she coughed since 1898. Her cough was constant and she suffered a good deal from dyspnea. There were impaired percussion resonance in left supraclavicular fossa, roughened respiration and sonorous râles in same area and extending to a point below the clavicle and into the supra-scapular fossa, on same side. Her weight was 119½ pounds. Five minims of a 2.5 per cent. solution of silver nitrate was injected into the left side of her neck, and she was given a teaspoonful of peppermint water three times a day. January 7 she presented herself and reported that cough and expectoration were very much improved. January 12, she was better in every respect. Physical signs were much improved; weight, 122 pounds. March 7, physical signs gone, except impaired percussion resonance; coughs scarcely any; weight 125½ pounds.

Case 2.—L., Male, aged 27, colored and married, was first seen Dec. 23, 1898, when he said that he coughed and expectorated a great deal during the last eight or nine years. Has anal fistula of some months' duration. His physical signs consisted of dulness, and moist râles in the left apex, extending to the middle of the chest in front on same side, also of dulness and a few moist râles in the left supra-scapular fossa; his weight was 120 pounds. Tubercle bacilli were found in his sputum. He had, under the direction of another physician, been taking half-teaspoonful doses of equal parts of comp. tincture of cinchona, and of syrup of the hypophosphites four times a day, for several weeks. December 27, his weight was 119 pounds, and his general condition the same. Injected 5 minims of a 2.5 per cent. solution of silver nitrate into the left side of his neck. No other internal medicine except that which he took before. December 31, weight, 120¼ pounds. January 2, 1899, weight, 121½ pounds. January 6, weight, 124 pounds. He felt much better, and his cough and expectoration were almost entirely gone. Injected 5 minims of silver nitrate into left side of his neck. January 11, weight, 126¼ pounds; injected 5 minims into left side. January 13, weight 129 pounds. Same internal treatment as before. Physical signs improved. March 10, weight, 132 pounds; injected 5 minims into left side. January 20, weight, 133 pounds. He now went to work and continued at it until November 20, when his weight had sunk to 127 pounds, and as he said he "caught a cold." On January 16, 1900, his weight was 128 pounds, and he felt good. At present writing, May 25, he weighs 130 pounds, is working, and feels strong and good. There are some dry, but no moist râles in his chest, and the dulness remains about the same as it was. His evening temperature is normal. When we consider that phthisis in the colored race always offers a very stubborn resistance to treatment the results in this one particular case may, perhaps, be regarded rather favorably.

Case 3.—J., male, aged 25, colored, was seen first May 5, 1899. Had lost two brothers and one sister of phthisis, and had been sick for three months with cough, expectoration, loss of flesh, poor appetite and sleep, chills, dyspnea and great weakness. There were dulness in lower half of left lung anteriorly and posteriorly, and moist râles in same area. Weight, 166 pounds. Injected 5 minims 2.5 per cent. solution into left side of neck, and gave internally the syrup of hypophosphites and strychnin. May 11, weight was 167 pounds. Injected 5 minims of silver solution on right side of neck. May 18, weight was 171½ pounds. May 25, weight was 174 pounds. Injected 5 minims on right side. June 1, weight was 177½ pounds. Injected 5 minims on left side. June 9, weight was 176 pounds. Injected 5 minims on left side. June 15, weight was 180. June 22, weight was 180. Injected 5 minims into right side. June 29, weight was 182½ pounds; temperature, pulse, physical signs normal.

When last seen, six months ago, this patient was in good health. How he is at present I am unable to say.

Case 4.—P., aged 47, white, came under observation July 7, 1899. Had lost in flesh; dyspnea, poor appetite and cough and expectoration since previous January. No family history of lung disease was present. There were lessened respiratory movement in right chest, impaired percussion resonance in right apex and subcrepitation in latter area. Weight, 125 pounds. Injected 5 minims of silver solution into right side of neck, and internally he received syrup of the hypophosphites and strychnin. July 14, weight, 130 pounds. July 21, weight, 136 pounds. Injected 5 minims into left side. July 28, weight, 140 pounds. September 4, weight, 143 pounds. September 7, injected 5 minims on right side. September 12, weight, 145 pounds. September 19, weight 147 pounds. Injected 5 minims on right side. September 26, weight, 148 pounds.

This patient is doing well now.

ADVANCED CASES.

Case 5.—L., age 35, female, with a family history of phthisis; came under my observation September 12, 1898. She was among the first of those who received the injections. She had been sick for three years, and at this time she coughed and expectorated a great deal, felt tired and weak, had lost in flesh, had a poor appetite, and occasionally spat blood. Tubercle bacilli were found in her sputum. Her weight was 96¾ pounds. There were dulness and moist and sibilant râles in supra and infraclavicular regions on right side. On this date she received 3 minims of a 10 per cent. solution of silver nitrate, without cocain, in the right side of her neck—a dose which produced more irritation than necessary. She had been taking the syrup of the hypophosphites and strychnin, and these were continued. She began to improve in general strength, cough, expectoration and wheezing in the chest, and in a week had gained a pound, and was eating better. In two weeks an abscess had formed at the seat of injection, which discharged, and she weighed 100 pounds. She continued to improve, and altogether received eight injections. She gradually gained in flesh until now she weighs 112 pounds and is practically free from all cough and expectoration. The physical signs, except the dulness, have disappeared.

While this patient did not gather much in flesh, I think it is difficult to make her gain in this respect, for in the early period of her invalidism I treated her in the hospital for four months, and with all the best food and nursing that the hospital could give her she only gained 4 pounds—from 102 to 106—in that time. On the other hand, she gained more readily under the silver-nitrate injections, although she was not receiving the good care and the nourishing food that she obtained in the hospital.

Case 6.—C., aged 69, laborer, was first seen September 1, 1898, when he said he had been coughing for eight months and had very profuse yellow and thick expectoration, dyspnea, palpitation, vertigo and a poor appetite, but was without a family history of phthisis. There were dulness in left supra- and infraclavicular regions and sibilant and crepitant râles over the whole chest. On September 27, he received 5 minims of a 1 per cent. solution of silver nitrate into the left side of his neck. October 4 he weighed 132¼ pounds. October 11, he weighed 132½ pounds, and received 5 minims of a 2.5 per cent. solution of silver nitrate into the left side of his neck. November 5, he was very much improved, his weight was 139 pounds, and 5 minims of the silver solution were injected into the right side of his neck. November 17, he coughed very little, had no expectoration and weighed 142 pounds: 5 minims of a 2.5 per cent. solution were injected into the right side. December 3, he weighed 142 pounds, and received 5 minims of a 2.5 per cent. solution into the right side. January 10, 1900, he weighed 143 pounds, and received same dose of silver on right side.

Case 7.—H., male, aged 42, came under treatment October 4, 1898. He coughed and expectorated for ten years. During the last two years his condition became much aggravated. He was tired, had much dyspnea, and spat blood occasionally. There were dulness in the upper and middle parts of his left chest anteriorly, and mucous râles in the same area. Weight was 133 pounds. Injected 5 minims of a 2.5 per cent solution of silver nitrate into left side of his neck. October 25, same injection; weight, 138 pounds. November 12, same injection; weight, 140¼ pounds. May 12, 1900, weight, 146 pounds. Feels well and has been working for a year. Physical signs, except dulness, have disappeared.

Case 8.—R., aged 43, blacksmith, married, and sick for one year, was seen first December 20, 1898. He then had a great deal of cough, profuse expectoration, chills, fever and night-sweats, and also spat some blood; morning temperature was 101.6. He had lost about thirty pounds in flesh, and weighed 137 pounds. He had pleurisy in the right lung, and partial infiltration of the whole of the lung on the same side.

He received the usual quantity of silver solution, and gained 7 pounds in six days after the first injection. He received no other medicine. He was very poor, on account of his protracted sickness, and lived on the charity of his friends. In six weeks after the first injection was given he went to work at his trade, and has remained at it ever since. He had not been able to work for eight months before he came under my care. He received altogether 18 injections, at the usual intervals, and gained altogether 28 pounds. All his physical signs cleared up and his symptoms disappeared.

FAR-ADVANCED CASES.

Case 9.—M., male, aged 47, chronic alcoholic, came under my care May 19, 1899. No family history of phthisis. He coughed a great deal and had profuse expectoration. His appetite was poor, bowels loose, and his breathing embarrassed, and he had lost a good deal of flesh. His weight then was 145 pounds. There was dulness in left apex extending to second intercostal space in front and to spine of scapula. In this area there were numerous moist râles and a small excavation below the clavicle. Tubercle bacilli were found in the sputum. He received nine silver injections altogether, together with strychnin, quinin and salicylate of soda, internally, and he gradually lost flesh for a month, when he weighed 137½ pounds. After this he gained, and two months later he weighed 142½ pounds.

A short time after this he went to work at his trade, and has been engaged at it steadily since. He now weighs 145 pounds, and has a normal pulse, respiration, and temperature. The physical signs have all disappeared, except the dulness, which still remains, although in a less pronounced degree, and the location of the cavity can scarcely be made out.

Case 10.—S. C., male, aged 25, clothier, came under observation September 8, 1899, when he stated that he had been coughing and expectorating for two years, also had night-sweats, much dyspnea, poor appetite; frequently vomited, and had lost flesh. He weighed 117½ pounds. There was dulness in the left supra- and infra-clavicular regions, together with moist râles over this area, and a good-sized cavity below the clavicle. Tubercle bacilli were found in his sputum. He began to improve in cough, expectoration, vomiting, dyspnea, night-sweats and physical signs after the first injection. He gained 12½ pounds in flesh and has followed his vocation for four months. The physical signs are very much improved, and he received altogether fifteen injections.

The deductions which may be drawn from the above-described action of the silver nitrate injections are—

1. That their best results are obtained in incipient cases, both in regard to the symptoms and physical signs.

2. That in most of the advanced cases they have a beneficial and, in some instances, an exceptional influence on the symptoms and physical signs.

3. That in the great majority of the far-advanced cases they ameliorate cough, expectoration, and other

symptoms temporarily, while in some instances their effects are apparently lasting.

In conclusion, it may be urged that the injections are too simple—too insignificant—to be of service in the treatment of phthisis, but any one who takes a broad and impartial view of the whole field of phthisiology must feel that the essential method of alleviating phthisis does not and can not consist of a complicated mechanism. This must be true, or in what other manner can we account for the so-called spontaneous cures—the healed phthisical lesions found in many lungs on the post-mortem table or in the dissecting-room, in which death did not result from phthisis? The cure in these instances—for cure it undoubtedly is—was simple; was not brought about by the administration of formidable doses of refined remedies, or was not the outcome of special treatment administered through complicated machinery and expensive paraphernalia; but in all probability it was the sequence of some change of habit, or was effected by calling into play some new influence of a terrestrial, social, psychic, or moral character, which diverted the abnormal movement into a channel of health so gradually and so imperceptibly as to elude, perhaps, even the consciousness of the patient. By this I do not wish to convey the idea that the cure of the disease is always readily and easily accomplished by art, but that this is possible in many instances does not admit of doubt; and if we are not able to do as well or better than nature, we ought to follow the example of the immortal Sims, who, in his despondency after the loss of his two first patients, tore his shingle off the window, threw it into the well, and vacated the town.

TUBERCULOSIS OF THE LUNGS TREATED BY COMPRESSION WITH NITROGEN AFTER THE METHOD OF MURPHY.

WITH FURTHER REMARKS ON THE RATIONALE OF THE PROCEDURE AND A RECORD OF EXPERIMENTS ON DOGS.*

A. F. LEMKE, M.D.
CHICAGO.

More than two years have elapsed since the idea of artificially compressing a tuberculous lung was put into extensive practice. During this time the pathology of compressed tuberculous lungs has been carefully studied, the literature has been more thoroughly searched for the expressions of clinicians and pathologists as to the value of compression of tuberculous lungs, such as results from pleurisy with effusion, either serous or purulent, and a series of experiments on dogs has been made to determine the effect compression has upon healthy lung tissue and to observe what changes, if any, are to be found in the pleura as the result of the prolonged contact with these membranes of agents used for compression, such as nitrogen and normal-salt solution. At the Columbus meeting of the American Medical Association I reported in detail 53 cases of pulmonary tuberculosis, in its various stages, that had been treated by means of intrapleural injections of nitrogen. Many other cases were reported more briefly. Since that time about 100 new cases have been treated. Time and space will not permit a careful record of these cases, and I shall direct your attention to those cases in particular that illustrate some of the points I wish to emphasize. Furthermore the results are of little practical value at this time.

It will not be a waste of time to refer again to the overwhelming evidence, clinical and pathological, bearing on this point that is to be found in medical literature. I will direct your attention to the paragraph which appears in Stoke's work on "Diseases of the Chest," published in 1844, in which he says: "In many cases, where the disease—speaking of pulmonary tuberculosis complicated by pneumothorax—becomes chronic, we may observe a singular suspension of the usual symptoms of phthisis; the sweats cease; the pulse I have known in some cases to become quiet and the patient may gain flesh and strength to a surprising degree." Blakiston, in his work published in 1848, in the chapter on the termination of phthisis, cites several cases of recovery that bear on this question. In the works of Jaccoud, Williams, Cornet, Fowler and Godlee, Paget and a number of older as well as more recent writers, may be found cases of pulmonary tuberculosis either very much improved or cured as the result of some such complication as pneumothorax or pleurisy with effusion which kept up for some time a more or less thorough compression of the organ.

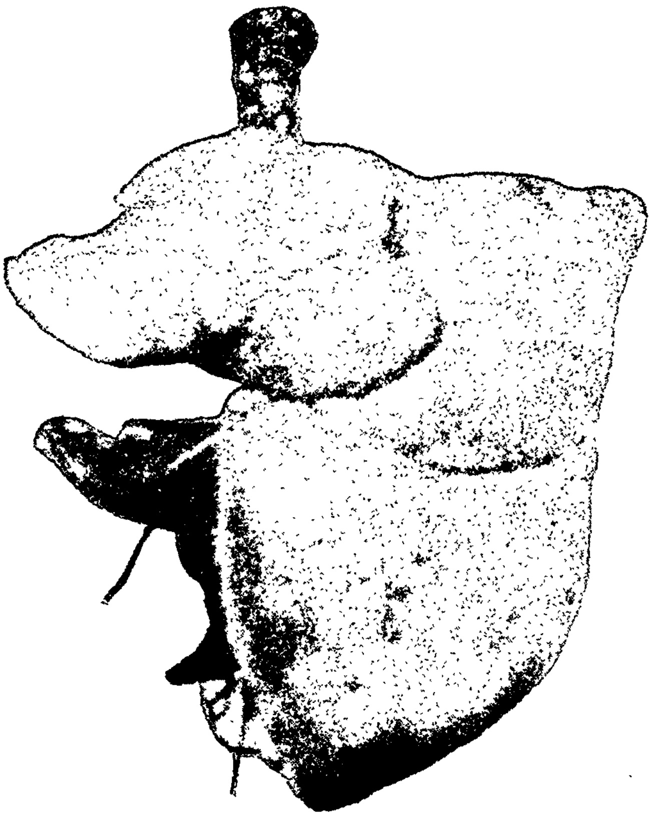

Fig. 1.—Normal right lung of dog.

You are all familiar with the very interesting chapter in the history of medicine that deals with the development of the operation of paracentesis of the thorax for pleurisies with effusion. You know how often this operation has been urged only to be condemned sooner or later by some one driven to do so by adverse experiences. Almost a constant warfare was kept up until Trousseau pointed out the indications for the operation that you are all familiar with. Since Trousseau's time some changes have been made in the indications, and I may say, without fear of contradiction, that at the present time, knowing, as we do from the experiments of Eichhorst and others, that more than one-half of the cases of pleurisy with effusion are tuberculous, the disease being secondary very frequently to tuberculosis of the lung, the tendency is to allow the fluid to remain, unless special indications arise to make its removal imperative. This question of the etiology of the ordinary pleurisy with effusion and the indications for the removal of the fluid has an important bearing on the question under discussion, but it is too complicated to be carefully considered at this time. I may mention, as briefly as possible, a case of pulmonary tuberculosis, complicated with pleurisy with effusion, that occurred in the practice of Dr. Murphy eight years ago, and that was largely responsible, I believe, for the ideas that led to his original experiment of injecting nitrogen into the pleural cavity to compress tuberculous lungs. The case was that of a middle-aged woman from LaSalle, Ill., who consulted him for pulmonary disease, which proved to be tuberculosis. Physical signs were detected over the entire left upper lobe and tubercle bacilli were demonstrated in the sputum. The woman was very much emaciated, the pulmonary disease rather widespread, and an unfavorable prognosis was made. Within a few weeks of her visit she developed left pleurisy with effusion, resulting in thorough compression of the lung, with a gradual improvement of pulmonary symptoms and finally a complete recovery from both pulmonary and pleural diseases. I had an opportunity of examining this patient two and one-half years ago, and the only evidence remaining of an old pulmonary tuberculosis was harsh, rough breathing over the left upper lobe. Symptomatically, she was perfectly well.

---

* Presented in a Symposium on Tuberculosis, to the Section on Practice of Medicine, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

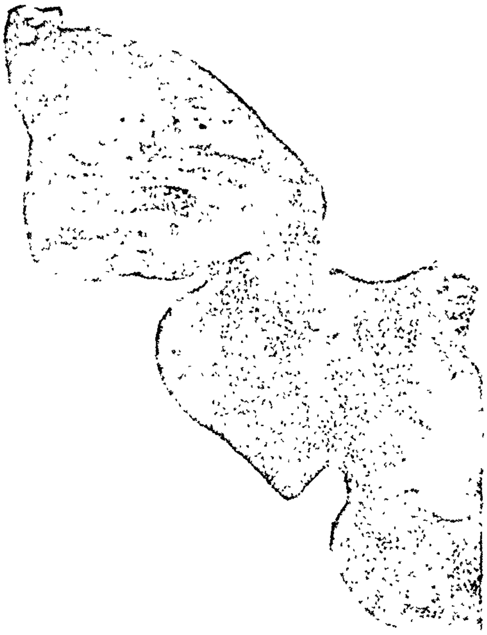

Fig. 2.—Compressed left lung of dog.

Last year Pinquet, of France, emphasized the desirability of maintaining pulmonary compression in pleurisy with effusion secondary to tuberculosis of the lung, and reported a case of tuberculization of the lung following thoracocentesis.

It has been urged that, if pleurisy with effusion is frequently, if not usually, secondary to tuberculosis of the lung, and even though many cases of pulmonary tuberculosis improve, or apparently recover, as a result of such compression, this change, it would seem, is only temporary, as is evidenced by the subsequent development of symptoms of active pulmonary disease. In this country we have the valuable statistics of Bowditch, who investigated the cases of pleurisy that occurred in his father's practice, and those of Osler, who reported, in his Shattuck lectures in 1893, that of 56 cases of pleurisy admitted to Johns Hopkins Hospital during the four years prior to his report, only four cases were known to have developed tuberculosis of the lungs subsequently. Späth[1] in an article, "Ueber Die Beziehungen der Lungencompression zur Lungentuberculose," cites a very interesting case to show the good effect of pleural effusion in preventing the dissemination of the infection into the compressed portion of the lung.

Observations on the favorable effect of compression of tuberculous lungs have not been limited to clinicians. Rokitansky made the observation that in spinal curvatures or other distortions of the thorax resulting in more or less compression of one or the other lung, tuberculosis of the organ so affected never occurred. In speaking of the effects of compression by pleural effusion, he said: "We may here further adduce the fact that the compression exercised by pleural effusion and a consecutive abiding increase of compactness of one lung as denoted by a sinking in of the thorax, in like manner extinguishes the tendency to tuberculosis."

It is a common observation in the dead-house that lungs that have been for some time tuberculous usually show considerable fibrosis in the neighborhood of the affected areas, and this is particularly true of diseased lungs that have been subjected to pressure such as pertains to empyema, in pleurisy with serous effusion, pneumothorax, etc. Knowing as we do that tuberculosis of the lung heals, and we know there is always a tendency in that direction, it is of prime importance to determine how such healing is brought about. It is by a process of cicatrization, as we are forced to admit by studying tuberculous lungs. This is true, at least of the ordinary productive lesions of the disease. It is barely possible that some of the purely exudative lesions may undergo a complete resolution. The rational procedure in attacking tuberculosis would seem to be by some means best suited to favor the fibrosis, which is recognized as an essential in the healing process of all pulmonary tuberculous lesions. A second and important point to be borne in mind is that a patient's life is not in great danger from the mere existence within his lung of a few localized tuberculous lesions, but of a dissemination of the infection throughout the lungs, and the question very naturally arises how, under ordinary conditions, it is brought about. The majority of cases

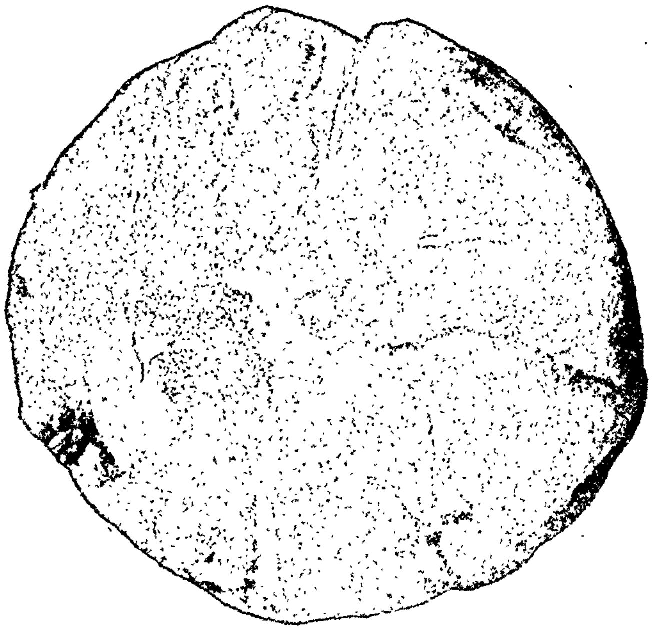

Figure 3a.

of pulmonary tuberculosis unquestionably begin with a single or with a few localized lesions usually in the apex nearer the posterior than the anterior surface, or, as Birch-Hirschfeld puts it, in the territory of the posterior apical bronchus. From this point the dissemination goes on more or less slowly through the bronchi and air cells, the lymph-vessels, and the blood-vessels. The two most important points to be considered in the local treatment of tuberculosis are: 1, how can we favor the fibrosis or cicatrization which constitutes the healing process of tuberculous lesions? and 2, how shall we prevent a dissemination of the infection that already exists? In answer to the first, let me call attention again to the pathological observations that an unusual degree of fibrosis is seen in tuberculous lungs that have been for some time subjected to pressure. Dunin[2] demonstrated, by a series of experiments on dogs that were made to determine the effect of compression upon the lung parenchyma, that in the neighborhood of small bronchi where slight infection had occurred there was a marked tendency to an overgrowth of fibrous tissue. When we stop to think of the mechanical condition of the lung we can readily understand that when this organ is subjected to a considerable pressure the various avenues by which infection is disseminated are occluded. The movements of the lung are diminished or absent and it is impossible for the softened material from foci that are breaking down to be aspirated into adjacent healthy portions of the organ. That compression must also exert a considerable inhibitory effect upon the lymph circulation in the lung is quite evident when we consider the physical state of the organ. Further than this, it is a well-known law of physiology that whenever an organ is put out of [illegible] circulation is impeded or abolished. Better than these theories, which explain in a very satisfactory way the imperviousness of a compressed lung to a dissemination of tuberculosis, are the findings in the dead-house, which show that whatever there may be in a compressed lung in the way of solitary or multiple tubercles, these lesions always bear evidence of age and of having antedated the condition which brought about the compression. Indeed, the question has been raised: Can fresh tubercles develop in a thoroughly compressed lung? For some time I have searched for material that will determine this question and I have never been able to find anything that might be looked upon as a recent tubercle in lungs that have been compressed for a considerable period. Relative to the same point, Fowler and Godlee[3] say: "It would indeed be strange if tubercular disease could make rapid progress in a lung which is bloodless and airless and in which, therefore, all the ordinary channels through which the virus of the disease is spread, viz., bronchi, vessels and lymphatics, are more or less obstructed." Rokitansky[4], again speaking of the curability of tuberculosis, says: "Tuberculous pulmonary consumption is unquestionably curable, as we may infer from the appearances not infrequently observed in the dead bodies of persons who formerly had more or less suspicious thoracic affections and subsequently recovered. It is only by an investigation of the conditions under which these natural cures take place that we can hope to arrive at a truly rational mode of treatment." And further, "If the abscess (tuberculous cavity) be not too large it closes by a gradual approximation of its walls, which finally come in contact and coalesce. We then find in place of the previous cavern a cellulo-fibrous mass in which the bronchi end in blind sacs. This is of most frequent occurrence in the apices of the lungs, where the coexistence of open caverns and the presence of obsolete and cretified tubercles indicate the nature of the process that is here going on. The obliteration of a cavity of considerable size always occasions a corresponding depression of the surrounding parenchyma and a cicatrix-like folding and puckering of the pulmonary pleura, which is most frequently and distinctly observed in the case of those cavities which are often superficially situated quite in the apices of the lungs. The thorax is also depressed to an extent corresponding with the size and number of the closing vomicæ, as is obvious from the flattening and slight depression so frequently observed in the clavicular region. This process is undoubtedly favored very essentially by certain circumstances, amongst which we may enumerate the local depression of the thorax, the contraction of the cavity in consequence of the diaphragm abnormally pressed upward by the contents of the abdomen, the development of the emphysema in the parenchyma surrounding the cavern and bronchial dilatation."

Aside from the fact that compression exerts a favorable influence over the healing process in tuberculosis by favoring fibrosis and by limiting the infection, that is, occluding the avenues by which the tuberculosis may become disseminated through the lung, we must consider the mechanical condition of a tuberculous lung from yet another standpoint, and I can do no better than to quote the remarks of Tidey:[5] "In health the respiratory capacity of the lung is commensurate with the semi-circumference of the thorax. The diseased lung may be regarded as decreased in bulk, so far as function is concerned, by the amount of lung tissue involved, and it follows that the best mechanical condition of respiration would be secured by reducing the thoracic cavity in proportion to the reduced bulk of lung. Natural processes of repair tend to secure these conditions, but only lead to complete cicatrization when the disease is of a limited extent. We find, then, clinically, a flattening of the chest wall, dislocation of adjacent organs or hypertrophy of the opposite lung. In so far as the inflammatory element in phthisis is concerned, rest and relaxation of the inflamed tissues seem indicated and essential to the healing process. The English schools aim at developing the latent resources of the lung so as to compensate for the loss of the respiratory surface." Tidey sums up the advantages of mechanical support as follows: 1, in early stages, to give comparative rest and relaxation to lung tissue; 2, in the stage of consolidation, to secure the same results, thereby limiting the risks of extension; 3, in the stage of cavitation, to promote the closure of cavities by directing healthy lung to encroach upon diseased areas, instead of relying entirely upon natural process of cicatrization; 4, diminished tendency to hemorrhage by reduced tension on vessel and cicatrical traction on walls; 5, the ultimate object is to obtain a smaller thoracic cavity filled with healthy lung instead of an enlarged thoracic cavity partly filled with diseased lung.

In a previous communication many references were made to the writings of some of the older authors on the subjects of pleurisy with effusion, pneumothorax, etc., complicating pulmonary tuberculosis. These it is useless to repeat. Many of the modern writers realize the advantage of compression in pulmonary tuberculosis. Cornet[6] says: "In fact, we find as the result of the development of pleurisy with effusion or of pneumothorax, not so seldom an improvement, even if temporary, of the condition (of the tuberculous lung) that is hardly to be explained other than that it is the result of the compression of tissues in the neighborhood of the tubercle."

The general proposition that compression exerted upon a tuberculous lung favors cicatrization, and therefore the healing process, and that, so far as we know, tuberculosis of the lungs always heals by fibrosis or cicatrization, can not be lost sight of. That there is an enormous tendency for tuberculous lesions in the lung to heal is apparent from the great quantity of statistics that have been gathered bearing upon this point. Some of the most valuable of these observations are those made by Harris,[7] who found that 39 per cent. of all individuals who died from causes other than tuberculosis gave evidence of healed or latent pulmonary tuberculosis. Schlenkir[8] found the same in 44 per cent. of the cases he examined. Birch-Hirschfeld[9] found, in an examination of 196 bodies dead from accidents, that 21.4 per cent gave evidence of healed or latent pulmonary tuberculosis. With this as a basis, we must conclude that, as far as local treatment is concerned, we have two important indications to be met. Both of these are pointed out to us when we study the pathology of the healing of tuberculosis in the lung. Given focus of tuberculosis in the lung, we must accomplish what nature always endeavors to do, first, to promote the development of scar tissue in and about the diseased area, and, until this is completed, to prevent the dissemination of the disease by occluding the various avenues that make this possible. Kurlow and Green (quoted by Cornet)' demonstrated that in areas of healed tuberculosis, made up entirely of scar tissue or of scar tissue enclosing calcareous material, no virulent bacilli were found. As long as the center of the focus is caseous, virulent bacilli are present and are capable of renewing the disease the moment the barrier is broken.

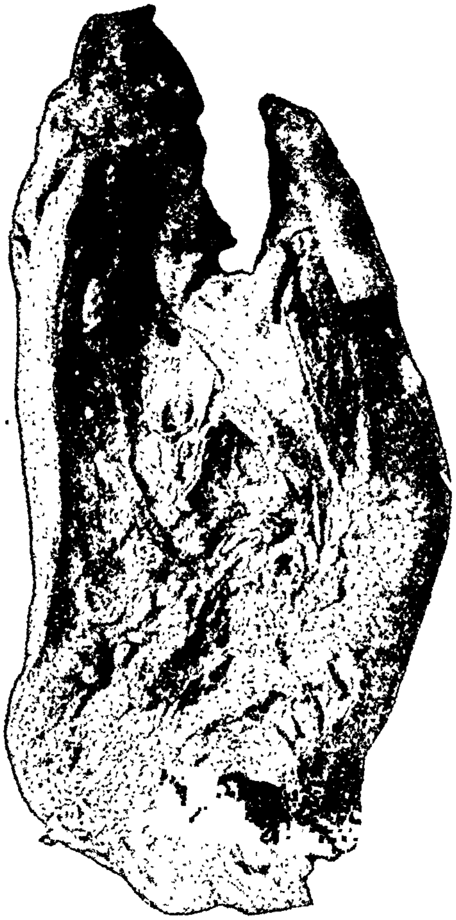

Figure 3b.

While there is no doubt that in the majority of cases the areas of healed tuberculosis consist of scars enclosing caseous or calcarous material, we may find as the only remnant of a tuberculous infection one or more thick-walled cavities, from which tubercle bacilli have disappeared. This may gradually and slowly heal as a result of contraction of its fibrous capsule, but much more commonly the mechanical conditions are such that definitive healing is impossible. In such cases these cavities may be a constant source of annoyance to patients, in that they have an active secreting surface which keeps up a continuous cough with expectoration. Case 5 of our first report[10] illustrates this condition very well. The patient was a strong, rugged man of 30, who had had tuberculosis of the right lung five years. During the first two years of his illness he coughed violently, expectorated freely and had several attacks of hemoptysis. His weight had been reduced from 160 to 117 pounds. During the third year he coughed and expectorated less and his weight reached 135 pounds. During the fourth year there was a gradual improvement. At the time of our first examination, September 5, 1898, he complained of having paroxysms of cough with much expectoration; he had no fever; his weight was normal, and he was able to be at work. There were no physical signs in the lung except scattered crepitant râles in the right lower lobe. Tubercle bacilli were demonstrated in the sputum. On September 7, 171 cubic inches of nitrogen were injected into the right pleural cavity. In this case we had supposed, on account of the paroxysms of cough with free expectoration, that a cavity existed which was more or less centrally located and which, therefore, gave rise to no physical signs. The compression was so thorough that the cavity was evidently emptied of its secretions, as the patient expectorated very freely immediately after the operation. He has been examined repeatedly since that time and every evidence of the disease in the lung had disappeared. There is no more cough or expectoration, and the patient even insists that the drum-stick finger ends and the curved nails are becoming less and less pronounced.

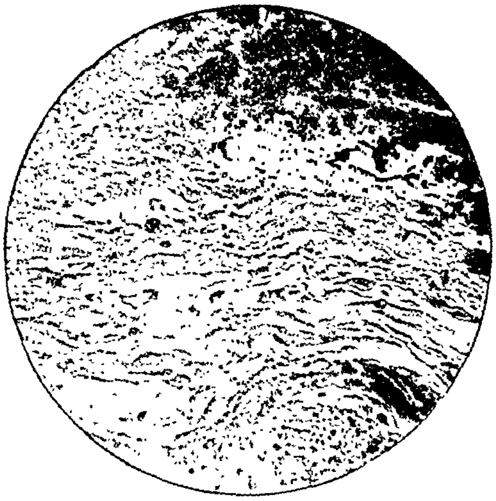

Fig. 4. – Fibroid area from compressed lung—high power. Section through a healed tubercle.

In our first publication on this subject, it was pointed out that pulmonary hemorrhage, the result of tuberculous disease, might readily be controlled by injecting nitrogen into the pleural cavity and thus thoroughly compressing the affected lung. Five cases of hemoptysis due to tuberculosis have been injected within the last year and in each instance it was possible to check the hemorrhage almost immediately. One of these, Mr. H. S., a very pale, anemic individual, consulted us for repeated attacks of blood-spitting. At the time of his first examination he was expectorating a bloody material, which upon microscopic examination contained great quantities of tubercle bacilli. There were physical signs over the entire upper lobe and a few scattered râles over the left apex. His weight was 147 pounds, a loss of ten pounds since the onset of the disease. The physical signs were so much more widespread over the right lung that it was concluded the hemorrhage had its origin there, and it was decided to inject the right pleural cavity with nitrogen and check the hemorrhage by thoroughly compressing the lung. The operation was repeated at intervals of one to three weeks until four injections had been made, when the physical signs had practically disappeared from both lungs; he had gained 23 pounds in weight, which was 12 pounds in excess of his normal weight, and all symptoms of disease had subsided. The hemorrhage was checked immediately after the first injection and has never recurred. In the other cases there was no difficulty in controlling the hemorrhage when it was possible to compress the lung thoroughly. At the last meeting of the American Climatological Society, H. P. Loomis, of New York, reported some cases of pulmonary hemorrhage treated by intrapleural injections of nitrogen and stated that he had never failed to control the hemorrhage absolutely. As early as 1885 Cayley[11] induced an artificial pneumothorax on the left side to check pulmonary hemorrhage. He simply made an incision in the thoracic wall, introduced a double tube and in that way created an ordinary open pneumothorax. During the night following Cayley's operation his patient had two attacks of hemoptysis, spitting up four ounces and two ounces of blood. This is the earliest record that I have been able to find of an attempt to check pulmonary hemorrhage by the induction of pneumothorax. The method of Cayley, it is very evident, gives rise only to a pulmonary collapse and is much more difficult and dangerous than the simple procedure of injecting the pleural cavity with nitrogen until an actual positive pressure is obtained and the lung not only collapsed but considerably compressed. Williams, in his work on pulmonary consumption, advised the introduction of a styptic solution—tannic acid—directly into the bleeding cavity. The objection to this procedure is that the exact point of bleeding can not usually be determined and that the method involves much more risk than the simple intrapleural injection of nitrogen. These cases of pulmonary tuberculosis associated with hemoptysis not infrequently develop a considerable fever and other symptoms indicating increased absorption at the site of disease or perhaps more or less acute dissemination of the infection, and it is interesting to note the rapid diminution of fever following the injections, indicating in all probability that the absorption of toxic substances is interfered with as the result of the thorough compression of the diseased organ.

One of the greatest dangers that confronts a patient who has pulmonary tuberculosis is the infection of his respiratory tract with organisms that give rise to what is ordinarily known as a secondary or mixed infection. The important part played by this secondary infection, such as the production of bronchitis, in that way favoring a dissemination of tuberculosis, and aiding in the softening and breaking down of tubercular foci is too well known to be considered in detail at this time. The avenues by which this secondary infection is carried into the various parts of the lung are occluded, thus favoring the chances of healing of the tuberculous lesion. Subsequent to the compression of tuberculous lungs, the fever and expectoration diminish so markedly that we are forced to conclude that the rôle of the secondary infections has been reduced to a minimum. Furthermore, it is known that so long as tissues infected with tuberculosis are also exposed to the action of pathogenic micro-organisms the healing process can not be completed. Whatever there is in the direction of cicatrization is undone by the pyogenic organisms, when they are present in sufficient quantities. This is very well illustrated by the work of Prudden, who demonstrated by experiments upon rabbits that the mixed infection is largely responsible for the exudative phenomena and the cavitation in lungs previously infected with tuberculosis. The tissue changes so essential to the process of healing of tuberculosis are very much interfered with by the mixed infection, and in the general hygienic treatment of tuberculosis of the lungs one of the first indications has been to get rid of the secondary element of the infection. As Cornet puts it, healing of a focus of tuberculosis in the lung is probably always altogether the result of tissue changes which diminish or inhibit the absorptions of proteins derived from the bodies of tubercle bacilli.

One of the most difficult propositions in connection with this work has been the selection of cases suitable for the injections. In connection with our earlier cases we made it a rule to inject only those in which the lesions were unilateral and in which but one lobe was involved. A great number of our cases, however, have been operated upon in spite of the presence of the disease on both sides and the two questions rather difficult to decide in these cases are first, will the remaining area of respiration after compression of one lung be sufficient to maintain life when the opposite lung is also more or less involved? and, second, will there be a disposition on the part of the functionating lung in the direction of rapid spreading of the disease already existing? Within the last year a considerable proportion of the cases operated upon have had bilateral lesions and in many of them there has been a marked general improvement in spite of the widespread distribution of the disease. It has been suggested that the increase of function called for in one lung when its fellow is compressed will tend to disseminate the infection; that the increase in the pulmonary excursions would favor an aspiration of infective material and that if compression and complete suspension of function in one lung will favor the healing of tuberculous lesions, a vicarious emphysema or hyper-function will have the opposite effect. This assumption is incorrect both in theory and in practice. It must be remembered that the lung is inclosed in a bony cage that makes it impossible for its excursions to be much increased beyond the normal. A number of the cases included in the first report show conclusively that there is no tendency to an increased activity of the disease in the functionating lung when its fellow is compressed. One of our cases (No. 49 of the first report) who developed a tuberculosis of the left upper lobe, some time after he had been injected for a tuberculosis of the right lung, has had eight injections on the left side without the slightest tendency in the way of a relighting of the disease in the right lung. At a recent examination both lungs were found entirely free from physical signs, except a pleural rub on the left side, and two months have elapsed since his last operation. In this case one lung or the other has been compressed at different times for a period of twenty months and at his last examination the patient was found nearly free from cough; his temperature and pulse normal and for the present at least he may be considered as having recovered from a bilateral tuberculosis that involved both upper lobes and the apex of the lower lobe on the right side. Forlanini, of Italy, in a personal communication to us about a year ago stated that he did not consider a bilateral distribution of the disease a contraindication to the compression treatment.

In several cases of very acute tuberculosis involving an entire lobe or the greater part of a lung, I have been called upon to compress the affected lung to stay the infection until the patient's general condition might improve sufficiently to admit of a change of climate and a continuation of treatment in the ordinary way. At the last meeting of the American Climatological Association, Dr. R. H. Babcock, of Chicago, for whom I have made a number of injections, stated that the compression seemed to him "to start the patients in the right direction."

On account of the frequency with which we meet pleural adhesions in the dead-house in bodies dead of tuberculosis of the lungs, it was believed that the majority of the cases that might apply for treatment would show pleural adhesions to such an extent as to make a compression impossible. In practice, however, we are forced to abandon the operation in only about 5 or 6 per cent. of the cases on account of pleural adhesions. It must be remembered that adhesions may be present here and there over the surface of a lung without interfering in any way with a thorough compression. Occasionally adhesions may be present anteriorly or laterally so that the needle must be introduced posteriorly and the lung compressed against the anterior thoracic wall. Mohr[12] studied the mode of displacement of the lungs in pleurisy with adhesion. In 23 cases in which there were no adhesions the lung was compressed in the usual manner against the vertebral column and mediastinum. Thirteen times it was compressed from below upward; 4 times from within outward; 4 times from behind forward; 4 times from before backward, and once from above downward. In some of our cases it has been necessary to puncture the thoracic wall at several points in order to find an area free from adhesions, and frequently we have in this way been able to bring about a considerable degree of compression in spite of circumscribed areas of adhesions.

It is impossible to determine by the usual methods of physical diagnosis whether or not adhesions exist. When a considerable pulmonary excursion can be demonstrated by percussion over the lower border of the lung, or when Litten's diaphragm phenomenon is present there is no doubt as to the absence of adhesions that will interfere with compression. There are many cases, however, in which these signs are absent, perhaps on account of the extensive infiltration of the lung, in which no adhesions are present and therefore it is impossible to determine whether or not the lung can be compressed until the needle has been introduced. On account of the danger of puncturing the lung and injecting the gas directly into the lung parenchyma, or perhaps into a vein, it is wise to determine whether or not the point of the needle is in the pleural cavity before attaching the tube. This can usually be very readily accomplished by instructing the patient to take a series of deep breaths as the needle is being introduced, when, if the point of the needle be within the free pleural cavity, a current of air can be heard to rush through the needle. In this way it is almost always possible to ascertain when the point of the needle is in the free pleural cavity. It is advisable to determine this point definitely, because of the slight danger from gas embolism in the event that the needle has been inserted into the lung and perhaps into a vein. With the exception of this point the technique of the procedure need not be repeated at this time. (See The Journal, Oct. 14, 21 and 28, 1899.)

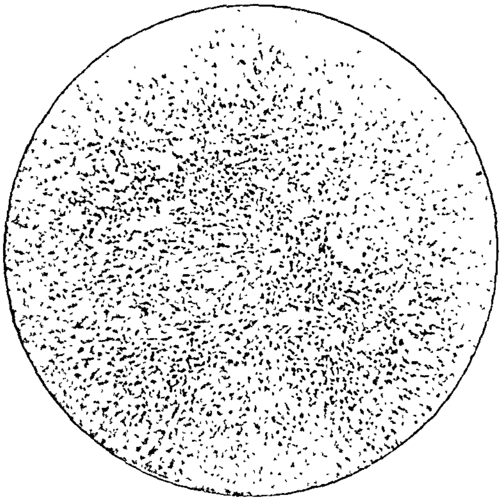

Fig. 5.—Section through acute tuberculous area in uncompressed lung.

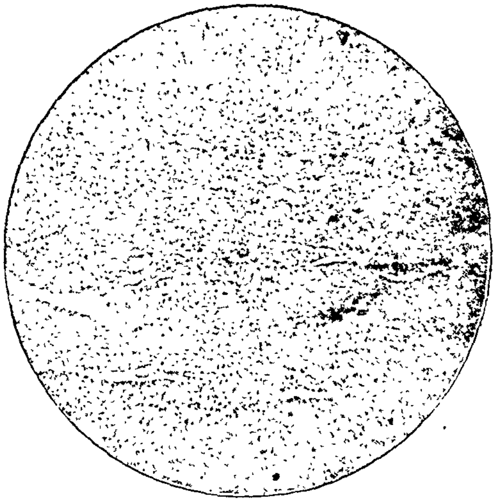

Fig. 6.—Section through old tubercle in compressed lung. Low power.

As regards the possible accidents of the operation I may state here that there have been no unpleasant symptoms in any of the cases operated upon since the one referred to in the first communication, and since the adoption of the intercostal compress no cases of subcutaneous emphysema have been observed to follow the operation.

The hemiplegia that is known to develop occasionally in connection with diseases of the lung or pleura, or during and after various operative procedures upon the thorax that involve the lung or pleura, can not always be explained readily, and is not always due to the same cause. It is possible that a small clot may be dislodged from a thrombosed vessel and carried to the brain, and may cause a temporary or permanent hemiplegia. In some cases undoubtedly the hemiplegia is to be explained on the assumption that a gas embolism has occurred. Some observers believe that the paralysis is due to a local metastatic encephalitis, and still others believe the pleural irritation in some obscure, reflex way is responsible for the transient or permanent paraylsis that ensues. The possibility of this accident should always be borne in mind, but its actual occurrence is too rare to be considered a serious objection to the operation. In a few cases patients have complained of numbness and tingling in the hand or the entire arm on the side of the operation, but this has always disappeared very promptly. The danger of hemorrhage from puncture of an intercostal vessel is scarcely to be given a serious thought, as no instance of it has occurred in the more than 600 thoracic punctures that we have made in connection with this work.

The danger of infecting the pleural cavity with the ordinary aseptic and antiseptic precautions taken is scarcely to be considered, as in all of the cases that have been injected there have been but two instances of pleurisy with serous effusion, and it is certainly unfair to conclude that these were due in any way to the injection of nitrogen.

During the past year we have been in the habit of making the injections somewhat more frequently than we did previously in order to keep the pleural cavity at all times well filled with gas and thus keep up a continuous compression of the lung for a period of several months, depending largely upon the patient's general condition and the physical signs detected in the lung when once the gas has been allowed to be absorbed.

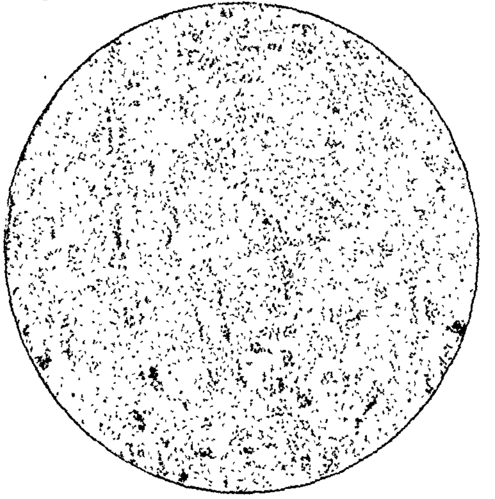

Fig. 7.—Section through acute tuberculous area in uncompressed lung. Low power.

The only objections that have been made to the procedure, so far as I am aware, are those of Samuel West,[13] who does not think that the rationale of the procedure is based on conclusive evidence. He believes that recent tubercle may be found in a collapsed lung, all evidence going to show that it developed after collapse, and that collapse of one lung is frequently followed by development of tubercle in the other lung.

In the Transactions of Clinical Society of London, Vol. xviii., West collected 24 cases of pneumothorax which recovered. The probable cause is specified in 18 cases. He states that 4 were certainly and 4 more probably due to phthisis; the others were due to emphysema, overexertion and injuries. West's own case was one of a young man who for some weeks had been an outpatient of the Royal Free Hospital and was thought to be phthisical. West says that "The cause of the pneumothorax we may assume to be phthisis, and the effusion of air appears to have acted in this case as the effusion of fluid often does, and for the time to have checked the progress of the disease."

The effect of compression upon the blood-supply of the lung has been the subject of considerable dispute and there seems to be some doubt as to whether a compressed lung is hyperemic or anemic. Some observers believe that the good effect of compression in pulmonary tuberculosis is due to the hyperemia and edema to which the lung tissue is subjected in its compressed state. Fütterer[14] reports a case in which the pneumothorax was due to rupture of the pleura pulmonalis of a tuberculous lung, and states that he "decided to wait some weeks to allow the patient to recover somewhat from the severe nervous shock he had experienced and to gain some strength as well as to permit the perforation to heal up, if the healing process could be established, and to put the supposed tubercular changes of the lung under the beneficial influence of edema and hyperemia, which are both present to a high degree in a collapsed lung, and which no doubt are powerful means of destroying the tubercle bacilli." In this connection it may not seem amiss if we refer again to the immunity from tuberculosis of individuals who suffer from valvular disease of the heart, giving rise to more or less passive congestion of the lung tissue. Eichhorst[15] says that a combination of pulmonary tuberculosis with valvular lesions of the heart is not so uncommon as was supposed. Statistics of Frommelt and Kidd show that from 7.2 to 8 per cent. of cases of valvular heart disease have tuberculosis of the lung. Potain found that 16.4 per cent. of cases of mitral stenosis are complicated with tuberculosis of the lung, and it is to be remembered that mitral stenosis, above all other valve lesions, gives rise to the greatest degree of pulmonary stasis, and therefore might be expected to give the greatest immunity to this disease. In Eichhorst's clinic 2 per cent. of the cases of tuberculosis of the lungs had valvular heart disease. On the other hand, there can be no doubt that in congenital stenosis of the pulmonary artery tuberculosis of the lungs is the rule. These statistics force us to the conclusion that in congenital pulmonary stenosis tuberculosis of the lung almost always supervenes sooner or later, but that mitral valve lesions do not by any means afford the degree of immunity to tuberculosis of the lungs that we formerly ascribed to them. That a lung thoroughly compressed must be comparatively anemic seems reasonable when we consider the mechanical change alone. The difference in weight between an atelectatic lung of a stillborn infant and that of an infant after a few respirations have been made would seem to be satisfactory proof of this. Schäfer and Symington[16] state, for example, that the lungs before birth weigh about one ounce and a half, but after com-

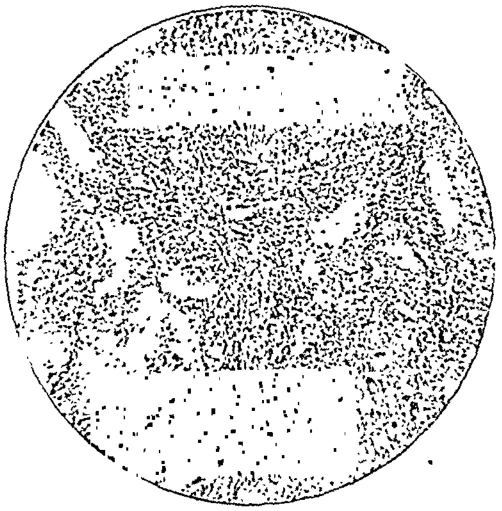

Fig. 8.—Acute tuberculous area in uncompressed lung. Low power.

plete expansion by respiration they weigh as much as two and one-half ounces.

During the past year we have made a series of experiments on dogs to determine the effect of compression upon healthy lung tissue, particularly the effect upon individual air cells. It has been urged that when compression of a lung has been maintained for a period of months, or perhaps a year, some of the air vesicles must be permanently damaged to the extent of partial or complete obliteration from prolonged contact of the opposing intra-alveolar surfaces. Clinically, from a consideration of cases of pleurisy with effusion and empyema in which the lung tissue is reduced to a compact mass and held in that position for a considerable period of time, we know that no great damage is done in the direction of alveolar obliteration. Even in empyema, in spite of pleural adhesions that are present wherever the lung is forced against the parietal pleura, expansion follows gradually and slowly as soon as the pressure is removed. In the majority of these cases the lung expands almost entirely, and would always expand completely but for the limiting adhesions. In the cases of pulmonary tuberculosis that have been treated by compression there has never been any doubt as to the re-expansion of the lung after the gas has been allowed to *become absorbed, even when the compression has been* maintained as long as six to eight months.

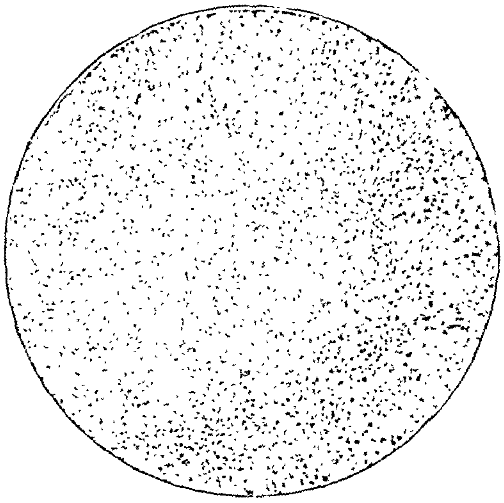

Fig. 9.—Acute tuberculous area in uncompressed lung. Low power. Marked necrosis.

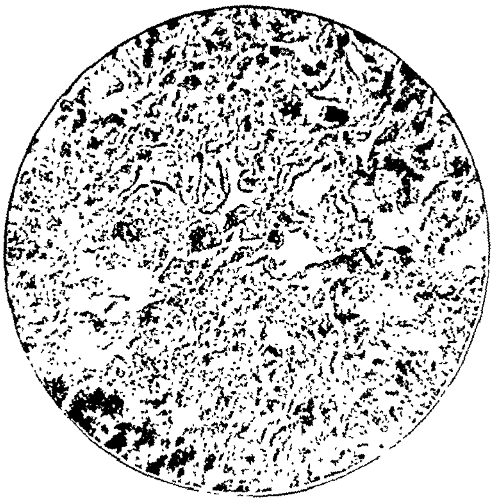

Fig. 10.—Area of compressed lung. High power. No tubercles. Air vesicles completely compressed.

To enable us to study the histologic changes in healthy lung tissue subjected to compression and to determine the effect upon the pleural surfaces, eight dogs were selected, the thoracic wall was prepared aseptically and nitrogen gas injected at intervals of from one to two weeks for a period of eight months. In four dogs normal-salt solution was substituted for the nitrogen. The gas was injected until the dogs became thoroughly dyspneic and until the respiratory sounds were altogether obliterated. I shall not repeat the records of these experiments in detail at this time, but limit myself to those findings that deal directly with the matter under discussion. No difficulty whatever was experienced in making the injections except that the mediastinum was ruptured in the second dog operated upon. This is an accident likely to occur in the dog, on account of the very thin mediastinal membrane. In the human subject the possibility of this accident need not be considered, as the membranes are very much thicker. The normal-salt solution was absorbed with greater rapidity, and, on account of its greater weight, it could not be injected in quantities sufficient to compress the lung so thoroughly as was the case with the nitrogen injections. Eight months from the time of the first injections the dogs were killed, the trachea clamped and both pleural cavities freely opened. The pleural surfaces were smooth and shining everywhere and, in fact, altogether free from changes, with the exception of a slight thickening of the pleura pulmonalis over a limited area in the sulcus interlobaris. The left lung was almost completely compressed, although it still crepitated slightly and floated in water. (Fig. 1.) In four instances the lungs were separated, a canula was tied into the left bronchus and inflation attempted. Over some of the dark, thoroughly atelectatic areas some little force was necessary, but at no point was it impossible to inflate the air cells thoroughly. The bronchi were then tied, the lung immersed in 5 per cent. formalin solution in water for twenty-four hours and then cut into small pieces for imbedding. Aside from slight epithelial desquamation, which was also found in the opposite non-compressed lung, no changes of any kind could be detected in the tissues. From the other four lungs pieces were prepared in their compressed state, and here also no changes could be detected.

These experiments merely proved, first, that nitrogen gas or normal-salt solution could be injected into the pleural cavity frequently and at short intervals without giving rise to infection or in any way causing untoward effects, and second, that healthy lung tissue may be kept in a state of thorough compression for a period of at least eight months without causing obliteration of air cells or in any way interfering with the re-expansion of the lung as soon as the cause of compression is removed.

At the last meeting of the Association I exhibited a specimen of tuberculous lung from a case of long-standing pleurisy with effusion which finally became purulent. The patient, Mr. M. A., aged 46, died as the result of his pulmonary tuberculosis soon after an operation for [illegible] He was admitted to Alexian Brothers' [illegible] on Jan. 19, 1900. Eight years before, he had developed a pleurisy with effusion on the left side, which was aspirated several times, but in each instance recurred. His attack of pleurisy had been preceded by severe cough with expectoration, the result of a tuberculosis of the left lung. In spite of the fact that the effusion persisted, he remained in good health for a number of years, and in fact was feeling well until three weeks before his admission to the hospital, when he developed a severe cough with profuse expectoration, great shortness of breath and extreme weakness. It is noted on the history that he expectorated much mucus and very little purulent material. The physical examination showed the signs of the presence of fluid on the left side, an aspirating needle was introduced and the purulent nature of the fluid demonstrated. On account of the extreme shortness of breath it was decided to operate in spite of the fact that the physical signs on the right side denoted a diffuse acute tuberculous infection of that lung. The patient died twenty-four hours after the operation. At the post-mortem the left lung was found reduced to about the size of the fist and thoroughly bound down by adhesions; the right lung was literally studded with fresh, grayish tubercles, varying in size from a millet seed to that of a pea, with an old thick-walled cavity in the apex. (Fig. 2.)

It is interesting to note in this case that the few scattered tubercles in the left (compressed) lung are made up of thick scars enclosing calcareous material, all evidence going to show that they are old, and in all probability antedated the pleurisy with effusion that brought about the compression. In the opposite lung there is an acute diffuse miliary tuberculosis. This further bears out the view that tubercles can not develop in a thoroughly compressed lung, because of the fact that the avenues by which the infection is disseminated are occluded.

CONCLUSIONS.

1. Tuberculous lungs after compression show much fibrosis in and about the foci of disease; hence, extension from these foci is less likely to occur.

2. Tuberculous lesions probably never heal by resolution, always by cicatrization—this is particularly true of lung tuberculosis. Hence, in attacking them it is rational to further the natural tendency to cicatrization.

3. The danger of pulmonary tuberculosis does not lie in the presence of one or more foci of the disease, but in a dissemination of the infection throughout the lungs or the body generally.

4. Healing is probably, as Cornet puts it, altogether the result of tissue changes which inhibit or diminish the absorption of proteins derived from the bodies of tubercle bacilli.

5. Areas of healed tuberculosis may consist of: Scars, perhaps enclosing caseous or calcareous material, or of cavities lined with a thick wall. Kurlow and Green (Cornet) have demonstrated that in areas of healed tuberculosis made up entirely of scar tissue or of scar tissue enclosing calcareous material no virulent bacilli exist.

6. Tuberculosis in the lungs spreads either by continuity and contiguity or by dissemination of the virus through, 1, the air-channels; 2, lymph-vessels; 3, blood-vessels.

7. Good effects of compression, locally, are brought about by the limitation of areas of disease already existing, by favoring fibrosis in and about these areas; by occluding the avenues of dissemination of the virus, and by compressing cavities to enable them, mechanically, to heal.

8. Other effects of compression are due to rest to the organ as a whole, emptying of secretions, prevention or diminution of absorption of toxic bodies, prevention of secondary infections, the diminished tendency to hemorrhage.

9. There is no evidence that fresh tubercles can develop in a compressed lung.

10. Pleural adhesions are less common than might be supposed from a study of material in the dead-house. The lung may retract in various directions on account of circumscribed areas of adhesion.

11. Healthy lung tissue may be compressed for a year or longer and retain its capacity for expansion upon removal of pressure.

12. The actual risk of the operation of intrapleural injections of nitrogen is very slight. No accidents have occurred since the first report was made.

13. Subcutaneous emphysema may easily be avoided by using the intercostal compress.

14. Uses of intrapleural injections of nitrogen: 1, curative in pulmonary tuberculosis for reasons mentioned above; 2, palliative—to prolong life for weeks or months, though the disease be too extensive to make recovery probable; to diminish fever and expectoration; 3, to check pulmonary hemorrhage; 4, to compress cavities, tuberculous and others, and establish mechanical conditions that will permit their healing; 5, to compress the lung just prior to surgical operations in which the pleural cavity is to be freely opened and to determine presence or absence of pleural adhesions before opening pleural cavity to drain abscesses or bronchiectatic cavities, cysts, etc.

DISCUSSION ON PAPERS OF DRS. FREUDENTHAL, ANDERS, EDSON, AMBLER, MAYS AND LEMKE.*

DR. VICTOR C. VAUGHAN, Ann Arbor, Mich.—I listened to the papers read with interest and with profit. The diagnosis of the prebacillary stage of tuberculosis is important, because that is the time when it should be diagnosed if we wish to accomplish anything in the way of treatment. I am much interested in the remarks made in reference to temperature as a means of diagnosing tuberculosis. I believe that the temperature curve in tuberculosis is much more typical than it is in typhoid fever, although there may be various conditions which affect the temperature curve, such as exercise, which influences it very much. I almost invariably have the patients take it at 8 a.m., at 12 m., and at 4 and 8 p.m. When the temperatures are taken at these hours the highest temperature will be found almost invariably at 4 p.m.

As to the possibility of complete recovery from tuberculosis, it is no doubt a question of *restitutio ad integrum*. In cases of peritoneal tuberculosis, where a laparotomy had been performed for that condition, and where, years afterward, another laparotomy was done for a hernia or something else, it has been found that the tubercular lesions had disappeared. Two years ago I took a large number of rabbits and inoculated them with virulent cultures of the tubercle bacilli; after a lapse of six weeks one-half that number had their abdominal cavities opened; in these cases we saw tubercular nodules, some of which were cut out and subjected to a microscopical examination, showing conclusively the presence of the tubercle bacilli, not only in the instances where there were tubercular lesions in the omentum and peritoneum, but also over the liver, which was dotted with tubercles. All these that were operated on lived, while the control animals all, or nearly all, died. Of course, statistics show us, as well as the observations, that tuberculosis is most easily curable. Rest, I am sure, is a great factor in the treatment of tuberculosis, and this is the reason why great benefit is obtained from sanatoria treatment. The question as to the amount of exercise and to what extent the patient should rest must be decided by each individual case. Where there is much temperature there must be complete rest. When the patient is not in a febrile condition, or the temperature is not above 100.5 or 101, considerable out-door exercise may be indulged in. Out-door life in the Western part of the United States or in Colorado is a good thing, but we do not utilize it enough in the treatment of tuberculosis—as we should. I recall a severe case of tuberculosis occurring in a patient who lived several miles from my office; this patient came every day to my office for treatment, rain or shine, cold or warm; the cough disappeared, the bacilli disappeared and the patient was apparently well. Out-door exercise is not as much utilized as it should be.

---

* Dr. Anders' paper was published last week; those of Drs. Freudenthal, Edson and Ambler were published elsewhere.

Dr. Mays' paper is certainly an interesting one. I had occasion some time ago to write an article on argyria, and I was surprised in looking up cases to find so many had developed tuberculosis when they were saturated with nitrate of silver. It does not seem to me that it is curative under these conditions.

Dr. DeLancey Rochester, Buffalo—Regarding the paper of Dr. Freudenthal, showing the effect of occupation, he mentions tailors particularly. It struck me that one of the chief dangers in tailors suffering from tuberculosis was from the dissemination of the disease. It is their habit to bite and wet the thread and then to go on sewing; in this way they can get the tubercle bacilli distributed widely. The tailor-shop is a marked factor in the spread of tuberculosis. I am also glad he spoke of the common occurrence of the disease of the upper air-passages associated with tuberculosis. In almost all cases of tuberculosis we find more or less disease of the nose and, particularly of the nasopharynx, and sometimes of the tonsils. The nasopharynx is particularly a nidus for the microorganisms. I have many cases in which a careful examination showed a secretion flowing in large amounts, quite persistent, and the washing away of the secretions resulted in disclosing other symptoms of pulmonary tuberculosis.

Dr. Anders referred to the prebacillary stage of tuberculosis; in this stage the temperature should be carefully watched. There is another point to which I wish to refer, the temperature as it occurs in the healthy. Observations show that there is a normal temperature curve, the lowest point being reached between the hours of 12 and 6 a.m., and the highest between 12 and 6 p.m. But these observations are not numerous enough to make statements absolutely reliable.

Dr. Edson has brought out the very great importance of rest. The index in regard to the question of rest is to be found in the pulse, the temperature, as well as the physical signs. To place a person at active exercise when he has a marked elevation of temperature, and other evidences of an active inflammatory process, or evidences of softening or a bronchitis, with danger of breathing scattered tubercle bacilli into the lungs and exciting the pneumonia, tubercular in origin, would be a great mistake. Rest is of great importance in the presence of numerous râles.

In regard to the case of Dr. Ambler, that of serum-therapy, it is not such a remarkable one when we consider that these cases are treated in a sanatorium, in a climate where cases recover without any other treatment at all, and where they naturally get well. So, I hardly think one can lay the good results obtained to any serum, particularly when we believe they will get well without it. The sanatoria treatment of tuberculosis is the best treatment these patients can get. At Saranac Lake these patients get nothing in the way of medicine except cod-liver oil, and nearly all cases get well. Rest and out-door exercise is the treatment.

Dr. Lemke's report is interesting as bearing on rest. His statement shows remarkable improvement in cases where there was a chronic pneumothorax. This year I had two cases under observation. In one the pneumothorax had persisted for several months. This case, after the development of the pneumothorax, progressed badly, became decidedly worse, the patient lost flesh rapidly, etc. In the other case, operated on without benefit, except some relief from the dyspnea, there was no pus present until after the operation. Neither of these cases improved by the spontaneous recurrence of pneumothorax, which persisted for several months. In one case at the General Hospital, the local lesion was a very slight one indeed.

Dr. Vaughan referred to cases that were saturated with nitrate of silver. I think he has mistaken Dr. Mays' meaning entirely. In Dr. Mays' treatment the silver nitrate is injected to prevent irritation of the vagus, and so affect the innervation of the lung, that was the point. The case was certainly interesting and instructive. He stated, however, that the cases were practically well. I wish he would tell me what he means by practically well. We know perfectly well that a large number of cases of tuberculosis improve under any treatment instituted. We should remember to treat the patient and not the tuberculosis simply; each individual case requires special study; some cases require one thing and some cases another. There was one case in Buffalo where there was an excavation at the apex, with infiltration at the other apex and at the base, and that case recovered without any specific treatment beyond out-door life and guaiacol in moderate doses.

Dr. S. Solis-Cohen, Philadelphia—My views on the causation of tuberculosis have been quoted. I have slightly modified them since that article was written. My present position is this: First, there is a fundamental trophic failure, congenital or acquired through privation, depression or excess. Then the invasion of Koch's bacillus—in rare instances another microbe, perhaps warranting a separate category for such cases—accompanied by definite histological changes and toxemia comparatively mild; then, with the invasion of pus organisms and similar microbes, a breaking down of tissue and a severe toxemia, with the phenomena properly called phthisis. As the trophic failure is fundamental in pathology it gives the clue to fundamental treatment. The patient's nutrition must be improved to the highest possible point. Rest may be necessary in some cases, and usually is when there is tendency to persistent elevation of temperature to or beyond 100 F.; but even rest should be in the open air when possible. Out-door exercise in proper cases is of the greatest value. In this connection I may recall attention to a case of recovery which I reported at the meeting of The American Medical Association at Newport, to illustrate the benefit of compressed air; that patient has remained well these thirteen years since that meeting, and keeps her health, I believe, by being out doors in all weathers. But I don't wish to go over the whole subject; I desire merely to speak of a few points omitted by others. One of these, and very important, is the early recognition of the tuberculous origin of indefinite attacks in young people and children. In many cases healed tuberculous lesions being found at autopsy, it is stated that there were no symptoms during life. It is possible that inquiry might elicit the fact that the patient, when a child, had had recurrent attacks with pronounced or vague chills, a sudden development of fever, and perhaps pectoral signs which were thought to be the symptoms of bronchitis or influenza or malaria or something else. I have seen many such patients, who will go free for months or years, when there will be a repetition of the same phenomena. They are not cases of influenza or malaria or typhoid fever, and while bronchitis or perhaps catarrhal pneumonia is manifest by physical signs, this is but a part of the morbid complexus. I am inclined to believe that these are cases of tuberculosis chiefly localized in the bronchial glands, and my experience indicates that some patients recover entirely and some later develop pulmonary tuberculosis. Regarding the diagnostic value of temperature, I lay particular stress on the rise which occurs between noon and 2 p.m. Often a temperature course, seemingly normal at all other periods, shows a distinct elevation during these hours. As a matter of convenience I select 1 p.m. for the first test. There is one exception; namely, patients who present an inverse temperature, i. e., higher in the morning than in the evening. The temperature of patients with tuberculosis is mostly affected by external surroundings. The heat of summer will sometimes send the temperature of such a one up one, two or three degrees.

In estimating the value of new methods of treatment reporting many recoveries, the element of time must be taken into consideration. Reports of recovery in six weeks may be thrown into the waste-basket; reports of patients remaining well six months need little attention; reports after one year or two years do not mean very much. I do not know just when to report cases of tuberculosis as well. I used to say four or five years was a sufficient time, but one patient reported well at four years died four years later of pulmonary tuberculosis. I have one patient now who has been well for seventeen years—my first case—treated by compressed air, iodoform, iron, raw-meat diet, etc. This I may report now to illustrate one line of treatment which has been successful in a certain proportion of cases.

Finally, I would ask members to read old books as well as new journals. Rush, in his classic on the treatment of consumption, calls attention to the value of rest and the value of regulated exercise in a way that impressed me greatly. He says: "I desire to call attention to the care with which exercise should be applied in cases of consumption in order that I may in some measure atone for the evil done by neglect of these precautions in my early practice."

Beginning with the slightest exercise, conformable to the ability of the patients and the stage of the disease, he advises that it should be gradually increased until they could be kept out of doors on horse-back. The stages were slow carriage-riding, faster carriage-riding, walking, running, horseback. Sydenham, before this, had called attention to horseback exercise as one of the best means of treating phthisis; while Beddoes, more than a hundred years ago, gave the hygienic regimen which is now so enthusiastically exploited by those "who only heard it yesterday."

Dr. S. A. Knopf, New York—I did not come here to speak, but simply to listen and learn. However, I gladly avail myself of the privilege to say a few words on the invitation of your honored Chairman. In listening to the many interesting papers on tuberculosis I have indeed learned much. The most important thing which the papers and discussions show is the advance we have made in phthisiotherapy, so that we no longer treat consumption, but the consumptive, and we no longer believe in a specific climate for pulmonary invalids. My time is too limited to discuss all the interesting points in the various papers presented here this afternoon.

To Dr. Freudenthal's experience with the sweatshop tailors as a class much exposed to consumption, let me add that I have observed two other classes of laborers also very frequently attacked by this disease, namely, assorters of dirty linen in laundries and Italian rag-sorters. I have not seen any statistics to confirm my observations, but it would be interesting to know the real extent of the disease among these classes of laborers. That I may not be misunderstood, I wish to say that I refer to the rag sorters who live and work often in the damp, dark, crowded basements of tenements, and not to the rag-pickers, who work all day outdoors and are much less exposed to tuberculosis.

Concerning exercise and rest-cure, I would say that both are valuable in the treatment of the disease in question, but that neither should be carried to excess. To have a patient lie for from five to ten hours on his back on a reclining-chair, with almost no interruption, as is sometimes practiced in German sanatoria, even if out-of-doors, I consider dangerous to the patient, for it may produce a pulmonary hypostatic congestion. The rest-cure is most valuable when alternated with short walks and breathing exercises, providing the patient has little or no fever. A temperature of 100 F. and over is an indication for quiet, and the less active exercise the patient gets the better. When the fever has become chronic gentle massage is well indicated, thus counteracting the disadvantages of a too-prolonged rest.

Dr. Mays' paper was certainly very interesting, but I fear we can not get the full value of his statistics as long as he does not tell us which of his patients had and which did not have the hygienic and dietetic treatment in addition to the nitrate of silver injections. We must admit that some patients' coughs improve and some get entirely well without any medicinal treatment. It may be interesting to recall in connection with this that Landouzy, of Paris, injects sterilized water into the supraclavicular region as cough remedy, and reports good success. My own favorite remedy for cough without expectoration is discipline. I tell the patient, in the language of my venerable teacher, Professor Dettweiler, that to cough in public simply because the throat tickles is impolite, like scratching the head in the presence of others when it itches; also that useless coughing only irritates the throat. At times I employ dry cupping to relieve cough and pleuritic pains. Of course, there are cases where the cough becomes distressing and where expectorants are necessary.

Before closing, may I come back to the cause of consumption among the toilers? Whatever we may do in the line of therapy or prevention by the sanatorium treatment, of which I am glad to say such favorable mention has been made by Dr. Rochester, let me tell you that as long as the law will permit tenements to exist, or to be constructed, which, owing to the lack of air and light and want of cleanliness constitute veritable hotbeds of tuberculosis, so long will sanatoria and special hospitals serve only as recipients of the supply of tuberculous patients daily created anew.

Before you leave this meeting let me beseech you to do your duty as physicians and citizens. You have a right to demand from your municipal government that the poor shall be better housed and shall no longer constitute a danger to their fellowmen. You have a right to demand that the hopeless, poor consumptive shall be isolated in a special hospital and the curable treated in a sanatorium near by. There is hardly a region in the United States where the climate would not permit a consumptive to be cured by the hygienic and dietetic treatment under careful medical supervision. It is no longer necessary to send our patients thousands of miles away. In our combat against this bitter foe of mankind we must not forget that consumption must be treated as much in its social as in its medical aspect.

Dr. R. C. Newton, Montclair, N. J.—I wish to relate a case which has proved interesting to me, and I think supplements some of the remarks just made. About two months ago a young lady, of 19 or 20 years, was referred to me with the following history: She had suffered from loss of vigor and from depression of spirits for some months; during this period her menses had been entirely absent. She had lost flesh and had shown an afternoon temperature of 101 to 102 F. The temperature had been taken at variable intervals. But I have no doubt that she had experienced a daily rise during at least a considerable portion of the time mentioned. She had not suffered markedly from anorexia or constipation. Her elder sister hinted vaguely at some love affair, which might have affected her health.

When I first saw her she was pallid, had some acne and complained of being listless and tired. Her family history was strongly tuberculous, so far as her grandparents, uncles and aunts were concerned. The history of her immediate family is very good. She complained of more or less dry cough every morning, but no expectoration. A careful swabbing of her throat produced a little mucus, which was examined in vain for tubercle bacilli. The blood was examined microscopically and showed some leucocytosis, the polymorphonuclear leucocytes being well marked. The red cells were comparatively healthy, showing only a few endoglobular changes. There were no malarial plasmodia. A careful auscultation and percussion of the chest seemed to reveal slight congestion at the right apex; so a tentative diagnosis of incipient phthisis pulmonalis was made. I referred the patient to Dr. James, of New York City, for further examination and for advice as to whether she should be sent to the Adirondack Sanatorium or not. Dr. James was disposed to regard the case as purely one of anemia and recommended large doses of tartrate of iron and potash, the patient to be carefully watched and her progress noted.

How this case may turn out is, of course, too early to assert. But there seems to be little doubt that a moderate diurnal fever may arise in chlorotic young girls from nutritional or metabolic irregularities and may subside without sequelæ, and very probably without treatment.

Dr. C. P. Ambler, Asheville, N. C.—Dr. Rochester is laboring under the impression that I am connected with a sanatorium in Asheville, and have read this paper as a report from such institution. Allow me to state that I have no connection with the sanatorium, and that these patients reported were not treated in a sanatorium. He probably has this impression from the fact that I was formerly connected with an institution in Asheville, but my connection with that institution was severed four years ago. Dr. Rochester has also stated that I make it appear that patients do not recover under creosote treatment. I did not say that. I stated that "where patients recovered under serotherapy they were not so liable to relapse as those treated by creosote and other allied drugs."

Dr. Knopf, in discussing my paper, has implied that I claim the results obtained were due entirely to medication. I distinctly stated that medication occupied third place. First, comes the hygienic supervision of the patient; second, good climate; third, medication. If all three of these methods can not be applied in a case, then the best thing the patient can do is to drop his doctor first, climate next, but under every circumstance hygienic supervision of the patient is absolutely necessary.

I am not here posing as a serum champion. I presented this report simply as a supplement to the report of the 106 cases presented last year, at which time my paper on sero-medication was read. I have shown that now, after the lapse of two years, 31 of the 106 cases were all back at their former employment.

Dr. Thomas J. Mays, Philadelphia—I think it is of great importance that we look on a new therapeutic question with leniency, for under the most favorable circumstances it is difficult to establish the correctness of any theory, and nowhere does this obtain more firmly than in the field of therapeutics, where the factors on which the theory is founded are so inconstant and variable. Some of the objections raised by Dr. Vaughan are that nitrate of silver may produce argyria, and be provocative of phthisis. I do not believe, however, that the small doses of 1/10 or 1/8 grain given once a week have the least perceptible general effect on the patient, and if my recollection serves me right, it appears that much larger doses of this drug are required to be given continually and for a long time before the symptoms of argyria are produced. Nitrate of silver is frequently given in daily grain doses for months in intestinal diseases without deleterious effect. That nitrate of silver may predispose to phthisis I believe, but the same may be said of lead, mercury, arsenic and other drugs. This is only true, however, when administered in large and toxic doses, and for long periods, as happens in the arts and manufactures. Indeed, I believe that anything which disintegrates, or diminishes the integrity of, the nervous system, as the above-named agents do in maximum doses, will predispose to pulmonary consumption. In small doses they stimulate, while in large doses they intoxicate.

Dr. Rochester asks me to define the meaning of patients getting practically well. This is a hard question to answer. Precisely, I believe that no tuberculous or phthisical patient will be entirely free and secure from the development of the disease if he lives a thousand years. The same may be said of many of us who carry inherited burden of this disease in our bodies and who, under prolonged physical or mental oppression, show a proclivity to the disease by the symptoms of a light cough, loss of flesh, impairment of appetite, etc. Therefore, I believe that a person who has been subject to this disease and recovers is never free absolutely from a subsequent outbreak, although he may be said to be practically well, especially if he is capable of performing work for six months, a year, or longer, provided he maintains his appetite, flesh, etc. The same is, however, also true of perhaps all chronic diseases.

Dr. Cohen referred to healed lesions of early tuberculosis usually occurring in children. I think it is true in many instances that children show a proclivity toward cure. I think they make quicker recovery than adults. I think in the "Medical and Surgical History of the War of the Rebellion" many cases of healed cavities and cicatrized phthisical lesions were noted in the lungs of soldiers who had died of other causes than phthisis.

Dr. A. F. Lemke, Chicago—I have but a few words to say in closing. In reference to the remarks of Dr. Rochester, I would say that I think every one is aware of the fact that a great majority of cases which develop pneumothorax in connection with tuberculosis result fatally; I believe that I am perfectly safe in saying that 90 per cent. or more of these cases of pneumothorax result fatally. There are two reasons: 1. On account of the valve-like formation at the point of rupture, so much air is forced into the pleural cavity that the patient dies of shock. 2. A more or less virulent infection of the pleura. Dr. Rochester states that in his case there was no pus, but this does not indicate that there was no infection.

It seems to me that the only practical way of getting at the question of the treatment of tuberculosis—not including prophylaxis—and the only rational way, is to consider how tuberculosis heals in a natural way. The great majority of lesions of tuberculosis, particularly those occurring in the lungs, heal by the process of cicatrization. In my synopsis, with which you are supplied, I have made a note regarding the statistics referring to the curability of tuberculosis. Every one is aware that Harris, of England, reported that 38 per cent. of individuals who died of causes other than tuberculosis showed healed tuberculous lesions in the lungs.

Fibrosis is the all-important factor in the healing of tuberculosis of the lungs. That compression will favor fibrosis can no longer be disputed. Furthermore, the danger from tuberculosis lies in the dissemination of the disease throughout the lungs. There are certain well-organized avenues by which this dissemination takes place, and these avenues are the air-channels, the lymph-vessels, and the blood-vessels. When compression takes place it occludes the avenues of dissemination of the virus and limits the disease to the parts originally infected. In that way the process of fibrosis circumscribes and permeates the original focus, which is transformed into a scar, and these scars are simply masses of fibrous tissue, or scars enclosing calcareous or caseous material. Our work, which has been carried on extensively for two years, has convinced me that pulmonary compression has an important place in the treatment of tuberculosis and that is based on unimpeachable clinical and pathological evidence.

ANGINA EPIGLOTTIDEA ANTERIOR.

REPORT OF THREE CASES.*

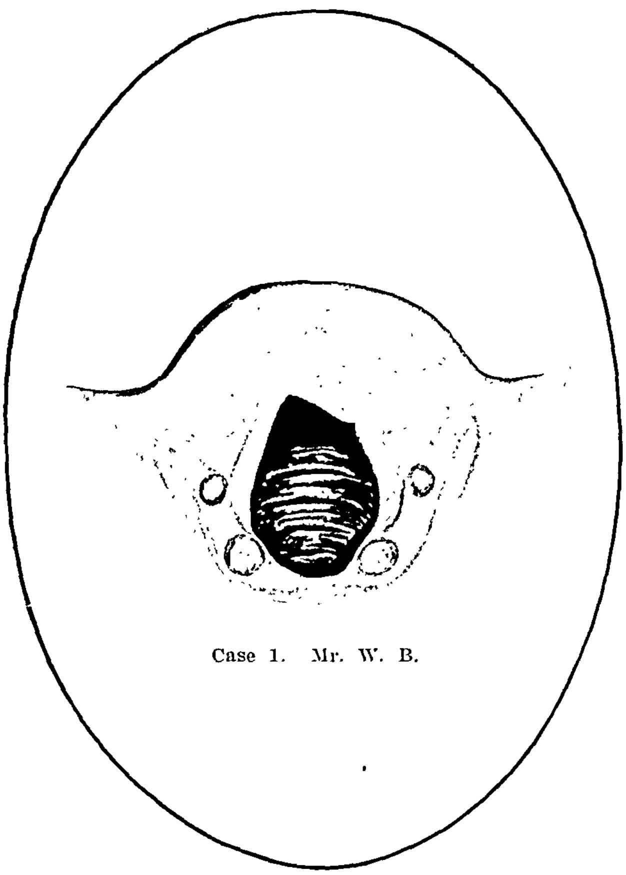
CLEMENT F. THEISEN, M.D.
Instructor in Diseases of the Nose and Throat, Albany Medical College; Attending Laryngologist to St. Peter's, Child's Hospitals, and Troy Hospital.
ALBANY, N. Y.

The name "angina epiglottidea anterior" was given to this interesting condition by Michel, in 1878. It is an inflammatory process involving the anterior surface of the epiglottis, as a rule confined to it, and accompanied by more or less edema, which is the characteristic feature of this affection. The larynx itself may be affected to a certain extent.

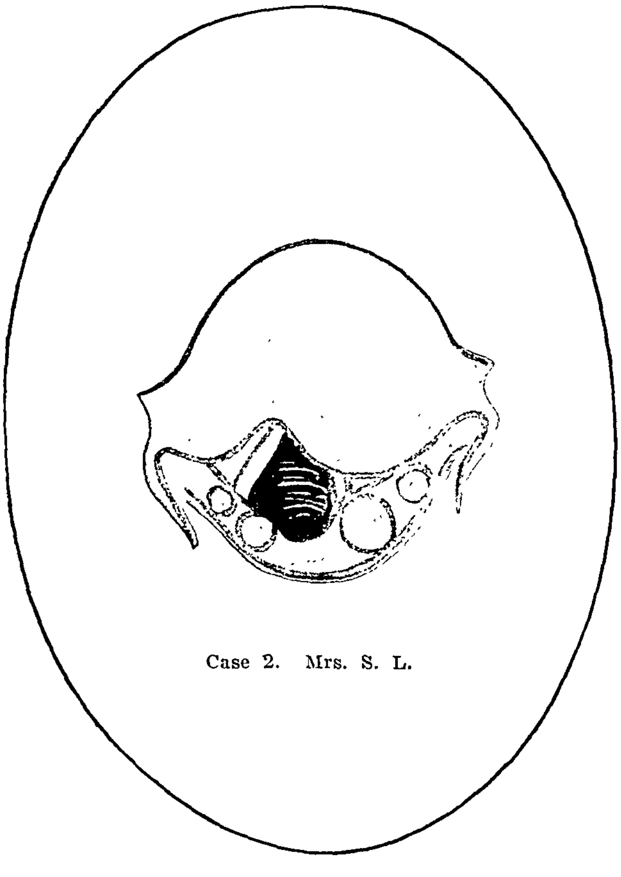
True angina epiglottidea anterior occurs quite often as a primary affection, and is a separate and distinct condition. This statement will, I think, be proved by

---

* Presented to the Section on Laryngology and Otology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.



Case 1. Mr. W. B.



Case 2. Mrs. S. L.

the report of the following cases. An inflammation of the anterior surface of the epiglottis, of course, sometimes follows an acute inflammation of the tonsils, acute pharyngitis and affections of the lingual tonsil. But in these cases the epiglottitis is merely a part of a general acute inflammation of the fauces, and must be distinguished from the primary or idiopathic epiglottitis. It must also be distinguished from a series of cases described by Arnold—30—in Burnett's "System of Diseases of the Nose, Throat and Ear," to which the term "acute miasmatic epiglottitis" was given. This will be fully considered after the report of cases.

Case 1.—Mr. W. B., aged 36. Was called to see him on the second day of his illness. He had been perfectly well before present attack, and in fact had always enjoyed the best possible health. His physician had carefully examined his pharynx, but could find nothing to explain the symptoms. When seen by the writer, the patient was sitting in a chair, with an anxious countenance, and presented the appearance of being quite ill. He complained of a very severe sharp sticking pain about the base of the tongue when he attempted to swallow. Attempts to swallow even a few drops of water brought on severe attacks of choking and coughing; there was pain on attempting to move the tongue; severe headache, restlessness, no appetite; voice was clear and there was no particular difficulty in breathing. The nose, nasopharynx and pharynx presented a normal appearance. The pharyngeal mucous membrane was not reddened. When the larynx was examined, however, the cause of the trouble was at once apparent. The anterior surface of the epiglottis was intensely inflamed, of a uniform bright-red color, and edematous. (See illustration, Case 1.) The larynx itself was not involved. Temperature 101 F., pulse 110. The patient was given an iced ichthyol spray, .5 per cent. solution, which was used every 20 minutes, and an ice pack was applied around the neck. Cracked ice was also frequently dissolved on the tongue. The next day his condition had considerably improved, although there was still pain and difficulty in swallowing. The inflammation of the anterior surface of epiglottis had subsided considerably and he felt better generally. The iced ichthyol spray was continued at half-hour intervals during the day, and was used at longer intervals as the acute inflammation subsided. On the fifth day he was practically well, although the redness and swelling of the epiglottis did not entirely disappear for several days more. A culture was not taken from the epiglottis in this case. He had not inhaled any irritating vapors, nor had he been exposed to cold.

Case 2.—Mrs. S. L., aged 40. Attack came on very suddenly, patient being in the best general health. She had not been exposed in any way and had not had a cold. Did not have a sore throat or even coryza before attack came on. First saw the patient morning of Jan. 4, 1900. Night before had been very restless and feverish, with headache, and great pain and choking when she attempted to swallow. She had also experienced much difficulty in breathing when lying down, and had to sit up in bed. On examination, nose and nasopharynx were normal and there was no evidence of any pharyngeal trouble. Mucous membrane of posterior wall, tonsils and faucial pillars was not reddened. Anterior surface of epiglottis was much reddened and so edematous that the laryngeal entrance was partly closed. Vocal cords were very slightly reddened and there was some swelling of the left aryepiglottic fold. (See illustration, Case 2.) Temperature 102 F., pulse 120. Calomel was given, and an iced ichthyol spray, .5 per cent. solution was used every 20 minutes, with an ice pack around the neck. Patient was also told to dissolve ice on the tongue frequently. Later in the day, as breathing was not much easier, I scarified freely, which gave her some relief. Next day patient was somewhat better and had not suffered as much during the night. Temperature 101.5. Epiglottis much less edematous and not as red. The laryngeal surface of the epiglottis was not swollen. The iced ichthyol spray was continued—every half-hour during the day—and, as in Case 1, at longer intervals for several succeeding days. She had been able to take absolutely no nourishment the first two days, but on the third could take some milk, as the difficulty in swallowing was much less. Epiglottis still very red, but edema both of that and left aryepiglottic fold had practically subsided. Temperature 101 F. third day. Her condition improved from day to day and in a week she was feeling almost as fell as ever, although the epiglottis did not get back to the normal condition for several days more. Immediately after scarification, cultures were taken from the epiglottis and examined by Dr. A. W. Elting, of the Bender Laboratory. The cultures showed a mixed infection of the staphylococcus albus and the pneumococcus. In the one culture the pneumococcus predominated. Examinations of the urine and heart were negative in this case. Patient had had no infectious diseases of any kind previous to her attack, nor had she ever had malaria. Injuries to the throat and the inhalation of irritating vapors could also be excluded as possible etiologic factors.

Case 3.—I am indebted for the following preliminary history of this case to Dr. MacFarlane, of Albany, by whom I was called in to examine the patient's throat. "Mr. D. F., aged 59, widower. Iron-worker; born in England. Has always been perfectly well except for injuries received in his work. About three weeks before present attack, had a general cold with muscular pains and headache. On May 11, 1900, he seemed perfectly well except for some slight pain in the back of the head. This became worse, and late in the night seemed to be more in the throat—left side. Tongue appeared to patient to be swollen and hard, and could be only slightly protruded. The jaws could not be fully separated and there was a marked sensation of choking, although at this time patient was able to swallow. Absolutely nothing abnormal was seen by ordinary pharyngeal examination. May 12. Throat more sore. Speech natural and voice clear. Tongue could not be well protruded. Temperature 102, pulse 96."

On May 13, the author was sent for. Patient's condition quite serious. Had been unable to sleep the night before and complained of severe pain around base of tongue. He could swallow absolutely nothing, as even the attempt to swallow a few drops of water brought on the most violent paroxsyms of choking and coughing. Temperature, 102. On inspection of the throat, the nasopharynx and pharynx were found to be absolutely normal. There was not the slightest evidence of inflammation. When laryngoscope was used, however, the epiglottis was seen to be enormously swollen and of a uniform redness. The left aryepiglottic fold was somewhat edematous with also some swelling of the right. An iced ichthyol spray .5 per cent solution, was used every 20 minutes, and an ice pack round the neck. Calomel and salines had also been administered.

May 14. Patient not much better. Pain in throat somewhat better but could still not swallow anything. Epiglottis was scarified, some of the serous effusion from the deeper tissues obtained, and four cultures taken.

May 15. Patient had had much better night and could begin to take a little cold milk. Edema of epiglottis much less. Temperature 101. The iced spray was continued at longer intervals. His condition improved from day to day and on May 18, a week after the onset of the attack, the epiglottis was not longer edematous, but still reddened and slightly thickened. The cervical lymphatic glands on both sides of the neck as well as the submaxillary glands had become swollen quite suddenly, and were tender to the touch. He made a good recovery, but had rather a slow convalescence. The cultures were examined by Dr. George Blumer, of the Bender Laboratory, and showed a mixed infection of the streptococcus aureus and pneumococcus. There were numerous colonies, and about an equal number of both organisms.

Etiology.—In considering the etiology of this rare affection, several important facts must first be mentioned. It must be remembered that one of the main reasons why an edematous condition of the anterior surface of the epiglottis does not involve the larynx itself, is, that the anatomical structure of the parts makes an extension of the edematous process very improbable. In other words it depends on the nature of the submucous cellular tissue. Hayek,[23] by his valuable experiments, has beautifully demonstrated this. The submucosa of the interior surface is abundant and the mucosa not tightly adherent, while on the laryngeal surface the mucous membrane is tightly adherent to the cartilage, and, with the exception of in the region of the nodulus, there is no loose submucous tissue. Hence, in cases of true angina epiglottidea, only the anterior surface of the epiglottis is involved. But, although the edema is usually limited strictly to the anterior surface, it may extend, when the edema is very great, by way of the thin submucous tissue of the pharyngo-epiglottic ligament, to the aryepiglottic folds. In mild cases, however, the pharyngo-epiglottic ligament is an effectual barrier, separating posteriorly, the cellular tissue of the epiglottis from that of the sinus pyriformis and aryepiglottic fold, and, as a rule, preventing the extension of the edema from the anterior surface. The laryngeal surface is not involved in cases of pure unmixed epiglottidea anterior; so that cases of acute miasmatic epiglottitis—as the six described by Arnold—must not be confused with the condition under discussion. Their etiology is also different. These cases are probably due to some vegetable or chemical poison present in the exhalations of marshes. This was so in Arnold's cases. In all his patients, young male adults, the attack came on after they had been punting for ducks on mud flats off the California coast. In all there was severe inflammation of the epiglottis—anterior surface—but swelling of the laryngeal surface as well, and in one, glottis edema was a complication necessitating tracheotomy. In one case too, there was edema of the uvula. For the sake of convenience in considering the etiology, angina epiglottidea anterior will be spoken of as acute epiglottitis or simply epiglottitis, which are really very good names for it, because, as before mentioned, an inflammatory process beginning on the anterior surface of the epiglottis, can not easily be accounted anything but a case of angina epiglottidea anterior, on account of the anatomical reasons already given. There is, of course, no doubt that an acute edematous epiglottitis may be secondary to inflammation of the tonsils, anterior faucial pillars or inflammation of the lingual tonsil.

Injury to the lingual tonsil or epiglottis itself, caused by swallowing any sharp or irritating substances or the inhalation of pungent chemical vapors, might also cause it. The swallowing of raw spirits, or very hot or sharply spiced drinks, or exposure to cold are also causes to be thought of. It is also a possible complication of Ludwig's angina or Massei's "acute infectious follicular glossitis." It may be part of a general edema of the fauces resulting from large doses of potassium iodid—as in several cases observed by the author. It may occur during the course of certain infectious diseases, such as measles, variola, scarlet fever, erysipelas, *septicemia, pyemia,* etc. Malaria might also be an etiologic factor. It may occur very suddenly with perichondritis, carcinoma or ulcerative processes due to syphilis and tuberculosis. Angioneurotic edema need not be considered, as the symptoms of acute epiglottitis are those of an acute infectious disorder, and fever is a constant symptom. In order to consider the etiology of primary epiglottitis, it will be necessary to review briefly the cases reported by different writers. In the opinion of the author, anterior epiglottitis is *very often* primary, and is an acute infectious process. A study of the following cases—which are *nearly all the authentic* cases on record—including the author's cases as well, will show that this must have been the case in the majority of the reported cases, although in most of them, there was no mention of a *bacteriological examination.* First, however, an error must be corrected. Meyjes,[34] who has reported an interesting case, makes the statement that Michel, of Cologne, was the first to report cases of this kind. He was probably the first to give the affection its present name, "angina epiglottidea anterior," but his cases are certainly not the first on record. Marsh[4] reported three cases of acute inflammation of the epiglottis in which the inflammation was undoubtedly confined to its lingual surface, and although he did not give it the name under which we describe the condition to-day, he nevertheless gave a most admirable description, which in all essential details, corresponds almost exactly with the disease as we recognize it. In his cases the attacks came on suddenly. Pharynx in all was entirely normal, while the epiglottis was greatly reddened and edematous. The epiglottis could be easily seen in the one case when the tongue was depressed. Patients were feverish. His accurate description and recognition of the condition are all the more remarkable when we consider that it was long before laryngology became an exact science. Long before this, however, in 1791, Mainwaring[1] described a case which is one of the first on record. A man, 40 years old, after exposure, was suddenly attacked at night with violent pain in the throat and complete inability to swallow. The pharynx was entirely normal. The epiglottis was greatly swollen and edematous.

Three cases were reported by Sir Everhard Home,[2] in 1808. These cases too came on suddenly. The epiglottis was greatly swollen, while the tonsils and surrounding parts were practically normal. Burne's[3] two cases were probably also of the same nature, one having a fatal ending. The pharynx was unaffected. Kesteven[7] reported two cases of epiglottitis, in 1849, and claimed that the disease was not met with except in connection with, or as a result of, inflammation of the fauces, tonsils or larynx. One case has been reported by Windsor[11] and four by Larsen.[8] Three of Larsen's cases were acute and one chronic. Two of the acute cases were primary and the chronic case was of syphilitic origin. This subject has also been alluded to by Wunderlich[9]—1856. A case that had a sudden and fatal termination has been reported by Tomkins[5]—1841. After death, the epiglottis was found to be greatly swollen. Other cases have been reported by Louis,[6] and Gibbs.[10] Another case that ended in death has been reported by Crisp.[12] A boy, 8 years old, after having been ill three or four days, died suddenly, apparently of suffocation. The autopsy revealed a swelling of the epiglottis, which was also very red. No other lesion was discernible in any part. Peculiarities of this case were the sudden invasion of the symptoms and the circumscribed form of the inflammation, which was confined to the epiglottis. Author considered death to be due to spasm of the glottis. No irritant had been taken. Fredet[16] has reported the case of a young man of 20. He returned home one night after a debauch and suddenly developed great difficulty in breathing. Symptoms rapidly increased in severity and suffocation ensued in a short time. Autopsy showed great edema of the epiglottis and aryepiglottic folds. When superior part of epiglottis was cut into, a large amount of pus was evacuated. There was no fracture nor necrosis of the cartilage. The suppurative epiglottitis was primary, followed by the edema, and glottis edema that caused death. Now, when we come to the more recently reported cases we find also a great similarity in nearly all, in the rapid development of the symptoms, and the almost constant presence of fever. This was particularly the case in the second one, that of a medical man, aged 38, reported by Milligan.[35] This case was considered to be of septic origin, as the drains in his house were in bad condition. The inflammation of the anterior surface of the epiglottis was probably not primary in Milligan's two cases, as in both the faucial pillars were congested, which is not typical of acute anterior epiglottitis.

In Meyjes' case the anterior surface of the epiglottis was greatly swollen and there was some redness of the right palatine arch. This case is a very good example of the disease. Michel[14] did not find the pharynx particularly affected in the six cases reported by him. Two of his cases were associated with swelling of the aryepiglottic folds; in one there was inflammation of a vocal cord, and two were complicated with Ludwig's angina. Moll[19] has reported a characteristic case in which there was redness and swelling of the anterior surface of the epiglottis, dysphagia and fever. Pel[13] has called attention to the condition, and also Wesseler.[14] Ruault[20] has recognized the existence of a primary circumscribed edema of the epiglottis. In some cases observed by Gottstein[22] no distinct cause could be ascertained. He questions whether edema of the anterior surface of the epiglottis is ever primary. Schmidt was[31] and still is[32] of the opinion that it is practically always secondary to injury or inflammation of the lingual tonsil. Kyle[36] states that "acute epiglottitis is not a separate condition." Störk,[18] on the other hand, twenty years ago recognized the fact that an "idiopathic epiglottitis" does occur under certain conditions. It is surprising that most of the prominent text-books on the nose and throat do not mention this at all or settle the entire question of the etiology of epiglottitis with a few lines to the effect that it is very rarely if ever primary. Browne[33] makes no mention of angina epiglottidea anterior as a separate condition, but believes that acute edematous laryngitis is quite frequently primary. As acute epiglottitis must be considered as perhaps a form of laryngeal edema, and has some of the same etiologic factors, there is no reason why it may not very often occur as a primary condition. Moure[15] too has mentioned the occurrence of primary edema. Out of 6062 autopsies held at the Charité, Berlin, 33 cases of edema of the larynx were found, 10 of which were primary. Bayliss[29] gives particular importance to malaria as an etiological factor in acute edema. Kuttner,[26] Semon and Hajek have done much to clear up the vexed question of the etiology of laryngeal edema in general, although both Kuttner and Semon are of the opinion that edema should not always be classified as a distinct condition.

Semon[27] claims that many of these conditions that have been classified in the past as separate and distinct pathological conditions, have a pathological identity. I certainly believe that the whole chapter of laryngeal edema will have to be rewritten some day. To dwell again briefly on my own three cases, we find that in each the attack came on very suddenly, with fairly high temperature, and symptoms of an acute infectious process. This is the evidence we gather too from the other cases that have already been discussed. While this is a most important point it still does not clear up the etiology, as in most of the later cases no mention was made of bacteriological examinations. And while it is true that in a very careful search of the literature absolutely nothing was found about the bacteriology, I believe that the cultures taken in two of my cases will help to clear up the etiology. We found that the result of the culture examinations was a mixed infection in both cases. In the one a staphylococcus and pneumococcus, and in the other a streptococcus and pneumococcus infection. It will be said at once that this does not prove anything, that all these organisms, particularly the pneumococcus, are found in the mouth quite frequently, both under normal conditions, according to Park,[24] who has often found the streptococcus, and also in cases of simple angina—Veillou.[25] This is, of course, well known, but one important fact must not be overlooked: The cultures taken in cases of simple acute angina, in which the streptococcus is nearly always found, are from surface swabbings. The swab is usually simply brushed over the surface of the mucous membrane. In my own cases, the cultures were taken immediately after scarifications—after the infiltrated submucosa had been cut into—and some of the serous effusion obtained from the deeper tissues. Then, too, the colonies were very numerous, and there were large numbers of the organisms. This gives the question quite a different aspect, and so far as these cases are concerned, they must be regarded as examples of "acute primary infectious epiglottitis." This is a reasonable deduction, and from a study of some of the other recorded cases, I believe we may come to the conclusion, with a fair degree of certainty, that the majority of them were also cases of the same nature, that is, acute infectious epiglottitis. It is, of course, a question, in the writer's cases, as to which organism was mainly responsible for the edema. It is known that the pneumococcus, when some of the lower animals are inoculated with it, will sometimes produce local edema. Welch,[37] in his interesting article on the "micrococcus lanceolatus," has brought this out. He quotes Foa, who distinguished a special variety of this organism. His pneumococcus he called diplococcus lanceolatus of the edematogenic variety. This edematogenic variety of the pneumococcus often produces, after subcutaneous inoculation in the subcutaneous tissue of some of the lower animals, widely spreading or local edema. Welch has also obtained cultures, which when injected subcutaneously, produced uniformly extensive local subcutaneous edema. So it is quite possible that in the two cases, the pneumococcus had something to do with the production of the edema. At any rate, it is quite clear that the edema was an acute infectious one, and that it was primary. In a case of primary edema of the epiglottis and larynx, reported by Levy and Laurens,[28] the edema was also considered to be of an infectious nature.

Diagnosis.—The diagnosis has been sufficiently discussed in considering the etiology, so that it need only be said that the condition can not be well mistaken for anything else. The uniform redness and swelling of the anterior surface of the epiglottis is quite characteristic. The author would enter a most earnest plea for the employment of the laryngoscope in all cases where patients complain of severe pain in the throat and inability to swallow, with a normal pharynx. It is, of course, not necessary to say this to a society of throat specialists, and it is only meant for the general practitioner. If the affection is not recognized early the patient's condition may become very grave and serious complications arise.

Treatment.—The treatment has been largely considered in the report of my cases. I would emphasize, however, the value of early scarifications. I thoroughly agree with Meyjes, in regard to the value of an iced ichthyol spray. It certainly relieves the acute pain and reduces the inflammation very promptly. If for any reason ice, or iced sprays can not be used, steam inhalations—medicated—would be of service.

CONCLUSIONS.

1. Angina epiglottidea anterior is very often primary and is an acute infectious process.

2. The term "acute infectious epiglottitis" is suggested for this condition as being more scientific, and more fully explaining its probable nature. It is, of course, understood that the inflammation and edema involve only the anterior surface of the epiglottis.

DISCUSSION.

Dr. Emil Mayer, New York City—I believe these conditions are really not so rare. I have seen cases and have scarified them with satisfactory results. They probably occur much more frequently than the presentation the Doctor has made would indicate.

Dr. E. T. Dickerman, Chicago—I remember two cases that may be of some interest in this connection, in which the inflammation, swelling and edema were limited to the anterior surface of the epiglottis. Both cases occurred in men who had been on prolonged sprees. It seemed to me that the edema was due entirely to the retention of imbibed liquids.

Dr. John F. Culp, Harrisburg, Pa.—I am inclined to think that these cases, as Dr. Mayer says, are not very infrequent. Two years ago, while working in the Vienna Polyclinic, I had a case referred to me. The man had been drinking and I found an inflammation of the epiglottis, with much edema of the anterior surface. I made an attempt to use scarification, but, probably due to my own unskilfulness, I was not successful, and I made an application of a 3 per cent. solution of nitrate of silver, brushing over the epiglottis very lightly. Knowing the prevalence of syphilis in these clinics, I thought I would give him potassium iodid. I prescribed 30 grains, three times a day, and advised that ice should be taken into the mouth as often as possible. I know he took the potassium iodid. Three days afterward he came back; he was still pretty drunk, but the inflammation of the epiglottis had almost disappeared.

Dr. John N. Mackenzie, Baltimore—I do not see how these cases differ from ordinary edema of the larynx. The causes of this condition we all know are as multitudinous as the stars. The result of the microscopical examination will depend entirely on the primary cause of infection and will differ very greatly according to that cause. This edematous condition of the epiglottis has been familiar almost in all times. The writers, long prior to the discovery of the laryngoscope, described hydatids of the larynx, especially affecting the epiglottis, and these hydatid formations, so-called hydatid tumors of the larynx, have been shown to be nothing but cases of edema of the epiglottis. Edema is very common in this situation on account of the loose anatomical structure of the parts. These growths attracted the attention chiefly of the writers of the early part of the century in France. Since that time the literature has been enormous. I think, with one of the speakers, that the cases are often due to too much whisky; the conditions are such then as to readily produce edema of the larynx. A famous case of which we all know is that of Washington.

Dr. Corwin—I wish to call attention to a case in which edema limited, so far as the larynx goes, to the anterior face of the epiglottis, occurred very recently in my practice. There was pharyngitis and stomatitis, and the condition was attended with considerable fever. There was some difficulty in speaking, owing to the swollen condition of the tongue. But the prominent condition which the patient complained of, and which I think was referable to the condition of the epiglottis, was that he was unable to swallow any food or liquid practically for several days. This might be interesting in connection with the subject presented.

Dr. John O. Roe, Rochester, N. Y.—As Dr. Mackenzie has clearly stated edema of the epiglottis may arise from an infinite variety of causes. A number of cases have come under my observation. In some that I recall, the condition followed the excessive use of alcohol, in some cases it was associated with diabetes, and in others it followed directly on acute inflammation of the fauces, caused by taking cold. I have observed it in many cases in conjunction with inflammation of the lingual tonsil. Many cases of edema of the epiglottis doubtless occur unobserved, and on careful examination of the epiglottis we will find some edema of the epiglottis in many cases of quinsy. We often have a follicular inflammation of the lingual tonsil at the same time that we have a follicular inflammation of the faucial tonsil, and the reason why it may be considered an infectious trouble is because of the readiness with which the tonsils form a feeding-ground or place for germs to propagate. If a bacteriological examination were made in the majority of these cases, I have no doubt we would find it a germ infection. The diagnosis is readily made with the laryngoscope; but in many cases by depressing the tongue with a curved or Kirstein depressor the epiglottis is plainly seen. The treatment of this condition is that employed in cases of edema of the larynx of an infectious nature, with special reference to the specific cause of the infection.
